I Notes taken in looking through Lindheimer's Texan Collection N°. 2

---

72 Ranunculus; similar to pusillus different: caulis basi
retrorsum hispido — petalis 5 oblongo linearibus
sepalis ovatis duplo longioribus, — nectariis
ovatis marginatis, apice latis. — might be called R. texensis; I hardly think it a
vid IV. variety of pusillus

Ranunculus trifoliatus granulatus near R ophioglossifolius
distant by cylindrical heads — small flowers
sepals reversed, = petals spatulate stamens
few — carpels tuberculate

89. Galium texanum glabrum annuum fol 4 (or 5)
fruit glabrous. — near Gal. aparinum?

Clematis heterophylla subsimplex
Lindheimeri crista hirsuta v. pubescens
76 Gaura ~~Lindheimeri~~ pilosa — Lancifolia; fol ut
obovatis obtusis, lyrato pinnatifidis, caulinis
sessilibus lanceolatis acutis sinuato-dentatis
magnis
rarissimis, inferioribus subintegris;
superantibus his deciduis
bracteis ovato lanceolatis acutis ovarium
ovarium calycis tubo infundibuliformi longe
petalis calyce pilosis reversis
oblatis. — fructu (immaturo) subpedicellato
hirsutis duplo longiore
ovato (subrhombeo) 4 angulato 4 sulcato
4 costis 4 interstitiis
lateribus ad medium carinatis, glabro nigrescente
fl. Apr. May. Texas (transversim
2-4 or 5 feet high in Apr. May & again in Aug. & Sept.?
Specimen from Septembers 1841 which appear
to be the same have somewhat smaller
flowers — segments of calyx only twice
as long as tube — fruit pubescente
ovate acute at each end subacerose
carinate angles the sides one nibbed up to
the middle.
plainte rugose

distinct from G. villosa Torr. to which it has
the greatest resemblance by the large knotty
larger petals subsessile fruit, short ovary
fruit similar to the description of J. trifetala but calyx segments much longer
than the tube fruit not closely sessile — I have seen it trimerous
Malva affinis s. non Lam to M. Papaver
distinguished by finer divided leaves more
nervose or ribbed calyx and pointed
carpels, which are blunt in M. Papaver.
carpels and seeds about half as large as in M. Papaver a much smaller Plant with flowers
apparently as large as in Papaver
— Spiranthes vernalis & similar to Sp.
vernalis & Apios &c.

Pyrola pappus carolinianus &c Papus white, — head of the rostrum with a hairy or woolly ring; — rostrum as long as the achenium
— pedicels and involucre a little tomentose
grasp
13 Cirsium filipendulum E. near C. discolor?
but heads twice as large, fibres of wool
enlarged, awake at base and top, hollow
filled with loose tissue leaves more divided than in C. virginianum
16. Liatris Carnosata & very near L. squarrosa
and some of the specimens of Torrey & Gray
appear to belong to this species.
L. glabra, radice tuberosa multiceps
caule foliosa; foliis linearibus basi
& Catalin semi amplexicaulibus
apice callosis obtusiusculis, punctatis
spicis densis brevibus, capitulis
subsessilibus, Ap. 5-floribus
squamis paucis adpressis (subortonis;) Pappo
lanceolatis arcuatis subulatis, & L. Gratis
exterioribus brevissimis
achenio glabriusculo pappum aequantibus plumosis.

II. Notes on Linden's Texas Collection

№ 2

11. Croton argyranthemum Chapagni folium. ramulis ramosis argenteo-lepidotis foliis integris obovatis obtusis, superioribus lanceolatis (petiolis) subacutis in petiolum attenuatis omnibus supra viridibus spars im squamosis subtus argenteo-lepidotis floribus ♂ ♀ racemosis, pedicellatis; ♂ calyce femineo, 5-partito, 5 stylis 3 bipartitis stigmatibus bifidis; — calyce masculo 5-partito lepidoto petalis 5 ovatis spathulatis basi (auth. Linnaeus) connatis — Texas. April 1842 — stam 15-20

vide last page.

Open woods,

the same!

perhaps = Cr. argyranthemum Mx

12. Stillingia sylvatica ? different appearance by the long pedicellate male flowers; from the true St. Syl.

Euphorbia glandulosa (Humb. & Bonpl.) Willd. sp. pl. 3 fidis, bis dichotomis involucris involucellisque lanceolatis basi attenuatis, margine albido glandulis petaloideis (subobsoletis, substipitatis) marginatis capsulis densae canatis seminibus rugis sparsis instructis

Texas September 1841 # plants lanceolate, acuminate, villosis

47 Cusenta ♂ ♀ bispidula ♂ ♀)

vide Cusenta

To Astragalus flagellaris ? is there a constant difference of this and A. distortus ? I find among my Texas specimens some with smaller deep purplish blue flowers, others with larger paler flowers but very dark blue tip of carina — legume more slender or thicker and even more wrinkled or smoother hair of calyx blackish or more whitish ?

Baptisia leucophaea β. laevicaulis stem smooth, glaucous, (not woolly). stipules and calyx smaller calyx more smooth teeth lanceolate subulate (not awl shaped) leaves frequently smoothish obovate or rhombic (not oblanceolate, woolly beneath glaucous

Amorpha glabra petiolatis

Lythrum ~~salicaria~~ E distinguished from L. alatum by the leathery (not membranaceous) leaves, with perfectly smooth (not scabrous) margins, and erect not recurved teeth of calyx ~~stamens not 6 stamens~~

Xanthium macrocarpum pyrene pauciformi nuda, glanduloso pubescente, rapae pubescente, calycis basin subulata pubescentes subaequante

Asclepias hirsuta ? picta alata (4-6') glabra glauca, fol. distantibus oppositis breviter petiolatis, basi lanceolata, horizontalibus longissimis margin revolutis, umbellis 2-3 V plurifloris (6-8) terminalibus nudis. 2-3 rectis) staminum genitale duplo superantibus

Fl. Guantica Lobis elliptic obtusis, Barkish swamps, Gulbert (near Lynchburg.)

Vigna pubescens rad. bilabiate. 4 forth,
middle tooth of lower lip longest, acuminate
upper tooth roundish, vexill. broadly
orbicular. 2 callosities along v. base
appendiculate carina acutish straight.
Stipules subbasifix. & base
lateral, strongly deep, vexill. pale yellow
stigma. acuminate, 3 nerved being
conduplicate subulate
sparsely pubescent, leaves bright
oval acute, peduncles longer, flowers
spiked. 10–15; legume oblong
white or blue, when ripe, black
with white hairs; seed black with white
hilum —
flowers yellow, as large as the
garden bean
Easily distinct from V. glabra by the pubescence and
the compressed legume; — from the Georgia
plant by the 4 pointed calyx, small flowers
variety on the brackish swamps with lanceolate
& linear lanceolate leaflets.
perhaps not different from V. glabra?

Amorpha nana n. sp. suffruticose, 1–3
feet high, much branched canescent; leaves
sessile, leaflets 16–24 pairs (small) elliptical
terminal orbicular, obtuse mucronate,
above canescent, below tomentose V. spikes
sessile solitary terminal, bracts (like stipules &
stipules) setaceous, flowers subsessile,
(calyx carinate & glandular) teeth of the calyx somewhat bilabiate,
broader larger 3 lower ones
two upper ones
lanceolate all acute and about as long
as the tube; vexillum orbicular obtuse
bright blue, ovary 2 uniporal silky
pubescent (2 ovulate) 1 seeded.
Calyx much larger, less tomentose and bilabiate open, not closed with

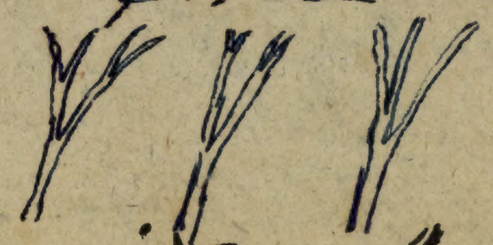
the inserted tooth, as A. canescens
perhaps between A. canescens & A. herbacea

Solidago microphylla, caule glabro, angulato
(plerumque colorato) virgatim ramoso,
foliis glabris, adpresse serratis, margine ciliato-
scabris, reticulatis, radicalibus spathulatis, in petiolum
decurrentibus, caulinis (superioribus) lanceolatis basi attenuatis
subpetiolatis, acutis, superioribus spathulatis
obtus. v. acutis, subintegris, racemis secundi elongatis
virgatim paniculatis, squamis involucri lineari-lanceolatis
acutis, viridinerviis; achaeniis pilosiusculis
fl. disci 4-6, radii 2-4. — Margin of woods
near Mount Sept. Oct with S. Altissima

Solidago Ludoviciana, caule glabro, simplici, basi
adscendente foliosa, foliis lineari-lanceolatis
mucronatis, basi angustatis, inferioribus elongatis, superioribus brevioribus
uninervibus, sparsim venosis, pellucido reticulatis
glabris (subcarnosis) integris, margine scabris
capitulis paniculatis contractis, pedicellis subangulatis
lateralibus secundis, angulatis scabriusculis
capitulis minutis, squamis lineari-lanceolatis
glabris, exterioribus brevibus, laxis; radiis 6-10
fl. disci 11-13.; achaeniis minutis pubescentibus.
Barren places in a high prairie west of Mount
Vernon June & July.

Similar to S. augusta T & Gr. but radius adscendens
fol. integra pedicelli elongati achenia pubescentia, pap.

Solidago decagynoides (see first page) whole plant covered with scales which are
pilosulate and attached at the middle (stellated hairs, membranously
connected), even petals and styles — Ovary sessile on
a fleshy disc. — The three styles are generally twice bifid; the
last division is more or less deep, or one of them wanting so
that the style appears 3 parted



Solidago decagynoides Torr.
Phys. II 268

III. Notes on a Texas Collection Dec 1842

Gaura exaltata ~~stems~~ erect, 6-9 feet high, villous-pubescent below, adpress, caescently pubescent above, much branched above leaves lanceolate, or linear lanceolate, attenuate at each end sparsely repand toothed, nearly glabrous ~~smooth~~ above pubescent with adpress hairs below; bracts lanceolate ~~leaves~~ segments of calyx about the length of the tube 2-3 times as long as the ovary, with longer than the ovate long unguiculate petals; fruit ~~sub~~ sessile oval oblong, ~~with~~ subacute, with 4 prominent obtuse ribs, and 4 inconspicuous intermediate ones."

Prairies on the margin of woods Houston Aug- to October. 6-9 feet high, ~~spreading~~ often covering exclusively large spaces of ground. ~~in~~

Distinct from G. biennis, by the long unguiculate petals, much smaller flowers and shorter not attenuate fruit; from G. parviflora by the short obscurely ovary. and much smoother leaves

Gaura Lindheimeri stem erect, etc as above

Gaura bractcosa stem erect, smooth, branching above, leaves sessile lanceolate, sinuate dentate glabrous, bracts linear lanceolate, smooth, ciliate much longer than the ovary persistent. segments of the hirsute calyx as long as the tube & the ovary together, petals? fruit?

Fort Parker, Groesbeck, Texas — July —

Lavauxia texana agrees perfectly well with Drummonds Lavauxia but ~~the~~ style of the disc flowers shorter than the tube and always sterile! rays 20-30. achenia ~~of them~~ striate sparsely pilose (ovaries pubescent) of the disc sterile 4 angular of the ~~disc~~ ray somewhat irregular, winged,

June 1843. — well distinguished both
by the elongated pedicels,
generally more
larger flowers, (which are of a similar shade
of colour) which are frequently found
in several distinct superior vertical
rows, & the generally narrower leaves, the upper
being nearly sessile; and by the oblong
or oval seed, which is usually obovate
in the other species. — The legumes of
It is probable that these species have
also are also transversely dehiscent —
but I have not seen ripe ones. —

36 Psoralea obtusiloba Torr. & Gr. Legume glabrous
Ramaj inate, glabrous on the upper side
as usual below. Calyx & legume
glandular. † Very near P. glandulosa.
floribus Torr & Gr; the specimens from
Illinois Lowry & Arkansas examined
by me have all glandular leaves,
a glandular calyx & ~~the~~ legume
(not glandulose Torr & Gr I. 300). Both are
distinguishable from P. obtusiloba by the
narrower, acute, not obtuse or emarginate
leaflets, thinner pubescence on the lower
surface of the leaves and smaller
stipules and the broad narrower and
more acute calyx teeth as the
light or yellowish brown seeds (with
P. obl., dark or blackish brown).

† Dry prairies east of the Brazos, Texas
near Jack flowering by the end of June.

It is

34. *Indigofera Caroliniana* Mill;
Clayey soil dry prairies; May to July
Houston to the Brazos, — flowers beautifully
variegated — Root thick ligneous.

33 *Tephrosia Virginiana* Pers *Holosericea* Ell

32 *Teph. mohrioides* Nutt *B. argentea*
Pubescens always white or silvery;
leaves mostly petiolate never subsessile leaflets
cuneate retuse or emarginate; or
both sides strongly ribbed; above smooth
below silvery pubescent; Stipules
somewhat persistent; calyx either
with woolly teeth equal to the tube or
with shorter Strigose teeth (Brazos) (Specimens from Houston
flowers perfectly white soon turning
to pale scarlet, Vexillum Green at base with the wings and keel
flowers on the Prairies from Houston
to the Brazos from the End of April
to August. The specimens from Houston
with the woolly calyx grow in sterile
sandy soil and flowered earlier
than those from the Brazos petiole Rachis, Later

oth species of this section petals yellow
with a brown red spot at base

The distinctive characters of
L. rigida are: ~~caule erecto~~
L. rigida. Rosh.: glauca caule erecto simplici
apice corymboso paucifloro; foliis
lanceolatis 3 nerviis nervis lateralibus
submarginalibus margine scabris,
stylis distinctis. —

20 Silene antirrhina β. subglabra
stem smooth; lower leaves ciliate
at base, upper ones scabrous on the marg;
upper ones with smooth margins

21. Silene antirrhina γ. laevigata
stem and leaves smooth with
entire smooth margins
Gibson Silene, near Thicket; April

The common form has stems scabrous
at base, usually upon the upper
internodes — all the leaves ciliate
on the margin and the lower ones
entirely scabrous on both surfaces
it grows together with the foregoing varieties

17 Hypericum gymnanthum; annuum
caule simplici erecto, quadrangulo
foliis ellipticis ovatis, amplexicaulibus
5-7 nerviis, pellucido-punctatis; cymis dichotomis
pedunculatis, aphyllis laxiflora. bracteis
subulatis, floribus pedicellatis, sepalis
lanceolatis, acutis petalis superantibus
staminibus 10-12, capsula ovata-conica
calyce vix superante, uni-loculari
seminibus flavis cylindricis longitudinaliter
costatis. —

yellow

the scant (not blunt) sepals, and the smaller more evidently ~~costa~~ ribbed ~~seeds~~, yellow seeds, in H mutilum they are larger and somewhat brownish and hardly ribbed. — The leaves of H. mutil are usuall oval or oblong, but sometimes they are also cordate at base. — Do the specimens of H. mutilum from Maryland Arkansas mentioned = Torr & Gr. I. 165 belong here? —

15 Helianthemum ~~dipetalum~~ Nutt. H. polifolium Torr. not Dec Prodr. III. 823. Dr prod I, 283. perhaps the name of H. stipes or H. heterandrum would be better.

13. Krameria lanceolata Torr. Dr. A. Braun has suggested that the natural affinity ~~with~~ of Krameriaceae is with Leguminosae rather than with Polygalaceae ~~Dr. Braun~~ At least in this species the two lateral glandulous petals cover in aestivation the stamens they cannot therefore belong to the ~~inner~~ interior circle. The ovary is uni-capellary (against the type of Polygalaceae) and one sided, like the fruit of ovary of Leguminosae. we find also in Leguminous plants which (show imperfectly) spirelled ovaries; but the two cells are always one on the side of the other not before the other, as in Polygala. — Krameria is then a pentandrous Leguminosa where the lowest of the stamens is mostly wanting, but sometimes in K. lanceolata we find on its place a sterile filament; ~~the lateral petals~~ ex. it corresponds with the free 10th stamen of Papilionaceae. as the 4 others (which are united in K lanceolata)

after carefully examining the number of flowers of different species of this Genus

but also on Listera and on Euphorbia corollata

122 Cusonia nemoptala Engl. & Sill Journ 45, 75

This is a smaller form, with somewhat lower flowers and earlier time of flowering and growing in dryer places, mostly on Celastrus multiflorus. further investigation will probably prove this C. bispidula Engl. It approaches C bispidula Engl and it is not improbable that further investigation of the living plants will prove this both to be only varieties of one very variable and widely dispersed species, for which we would suggest the name C. porphyrostigma, as all forms which would belong to it have are distinguished from all the known N. American Cusonias by the purplish brown stigma. Another very remarkable variety is:

123. Cusonia nemoptala Engl. β. littoralis vide Cusonia Supra

124 C. cuspidata vide Cusonia

125. C. pentagona γ. subglauca Sill. Journ. 45, 76

Wet prairies, mostly on Boltonia diffusa 128

126 C. verna. Engl Sill Jour. 45. 74

Note to C. cuspidata. — Two other new north american species have been kindly communicated to me by Dr A Gray as the W S Sullivant, who have collected the last fall (1843) on the South Alleghanies.

Cusonia oxyantha vide Cusc.

Cusonia (Lepidanche) compacta Chois. ?

128 Convolvulus aquaticus Wall. On wet Banks, west of the Bridge; comb. often ten feet long. —

Is this equal ~~species~~ by the hairy leaves, calyx not repand dilated fruit & [illegible] but not in the form of leaves — The ~~Corolla~~ ~~calyx~~ is equals with Calyx and not so sharply emarginate;

127. Convolvulus sagittifolius Wall; pedunculus one flowered, rarely two flowered, & with longer than the petiole, ~~but with~~ two minute deciduous bracts in the middle. Seeds ~~with two~~ woolly hairy on the edges —

In ~~pastures~~ near Houston, climbing on grass etc 8–15 inches high;
In thickets near the coast 2–3 feet high.
June — July. to September

11. Lindheimeri Collection 1843.

~~Ann Harbor~~

——— n. gen. calyx 5 fidus, corolla tubulosa, bilabiata, labio superiore ~~bifido~~, emarginato inferiore trifido lobis rotundatis ~~ovatis v oncavis~~ staminibus 4, antheris ~~glandulosis~~ bilocularibus superioribus majoribus inferioribus minoribus (incompletis ~~subinde~~ rarentibus Lindh.) capsula bilocularis, dissepimento contrario valvis ~~duabus~~ adhaerente, seminibus plurimis (12–20) retinaculis suffultis.

Planta perennis aquatica habitu Justiciae ~~corolla tubulosa~~ staminibus 4 et capsula polyspermum distincta.

glabra
Spinguis n. sp. caule erecto simplici, foliis oppositis ~~linearibus~~ lanceolatis elongatis, margine obsolete — serrulatis floribus ~~glomeratis~~ sessilibus — in axillis foliis glomeratis, corolla rubra vix superante; capsula linearis lanceolata acuta.
near Houston

In swamps, ft. Sept & October.

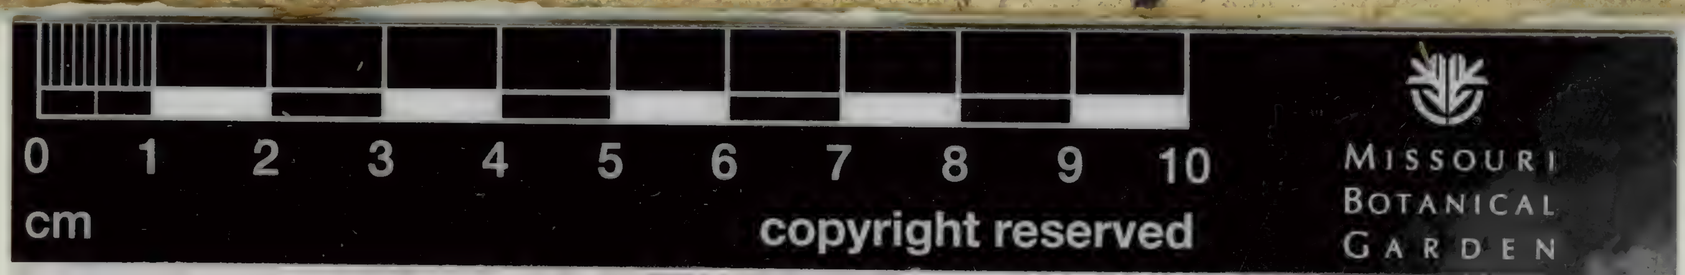
end of the third letter to Gray

182. Polygonella enodes. n. sp. — you tell me the genus is known; if the species also known? if not enodes may be a good name if it distinguishes it from other species of the genus.

Polygonella: ~~calyx~~ perigonium 5 partitus staminibus 5 exterioribus forma 3 interiora petaloidea obcordata, cum stylis 3 capitellatis alternantibus; nux triangularis ~~stylus~~ perigonii segmentis 3 interioribus ~~augmentatis~~ inclusa, 2 exteriores minores (~~reflexis~~ distinctum?)

~~Herba~~ suffruticosa, a Ramire ~~toto~~ numero locis ramosa perigonii ~~habitu~~ et stigmatibus capitatis non ~~clavatis~~ penicillatis et toto habitu — a Polygono stylis ~~divaricatis~~ in liberis et nuribus solum laciniis perigonii 3 interioribus multo augmentatis tertiis

P. enodes, glabra, glauca caule suffruticoso ramoso foliis ~~lanceolatis~~ linearibus, fasciculatis, oblongo linearibus obtusis, mucronatis, floribus spicatis spicis paniculatis, bracteis obtusis ~~obtusis~~ acuminatis; floribus pedicellatis



laciniis perigonii pubescentibus, pedunculis
inferioribus ovatis subcordatis, caulinis
extensis reflexis, multis minoribus.

Ranges 16 miles west of Mt Tolly
on the Bogos. — July. — Stems 1–1½
feet high, many from the same root
somewhat diffuse rose; leaves with
ochreate stipules, apparently somewhat
fleshy. — This plant is more closely
related with Polyg. than with Rumex
but the fruit resembles the last genus
much more than the first.

— Among th Polygona is one nearly related
with P. mite & pensylvanicum; which
I have called P. texanum: others is
ericetis; perigonii glandulosis is,

Pl. 5–6 angles 2 grains, seeds brown
— a large plant 2–3 feet high,
growing in swamps, leaves 5–7 inches
long, pink brown.

169. Erigonum flavum Nutt. ?
I doubt whether this be Nutt's plant
but I have no specimens nor drawings
to compare and must leave it
undecided.

169. Shilling Convolvulus Nuttallianus R. ?
Sl. Nuttallianus Lin. ?

1705 Sl. Cipatha — male flowers
seem to be nearly sessile, but in
our specimens they are long pedicelled.

Borya nov. ? Polygonum flowers, pubescent.
new species ? Ra pubescens ?

Fraxinus nitida: amongst the common
form ~~specimens~~ is a specimen, very similar
but climbing! Lindheimer thinks it a
variety, ~~and it may be so~~ but
the leaves are narrower with shorter
petioles. The flowers not ~~many~~ long spikes
as in F. nit. but a few 2–4 together
flowers, fruit, — 2 fruit specimens only,
much smaller. It may be a distinct
species

174 Euphorbia bicolor n.sp. annua caule erecto, basi ramoso
foliis subsessilibus, lanceolatis, ~~lanceolatis~~ v. linearibus
cuneolatis basi obtusis cuspidatis pilosis, v. villosis
umbellae trifidae ramis bis dichotomis, foliosis,
bracteis lineari lanceolatis basi attenuatis
margine decoloratis membranaceis,
glandulis 4 v. oblongis (villosis) margine petaloideis, obtusis
capsulis dense lanatis, sensibus rugosis
sulc

~~Species proximus to~~

E. bicolor, bracteis margine membranaceo
angustissimo v. subnullo; foliis latioribus

Prairies near Houston Linn to Fayette.
E. wet saline prairies near Lynchburg. —
Annual, 2 to 4 feet high, a splendid
species, resembling much E. marginata Pursh
distinguished by its narrow leaves and bracts
& by the villous pubescence. — Our
specimens of E. bicolor have wider leaves
and the bracts are nearly entirely green
but they are poor specimens, not fully developped.

fl. mast. apice spina pubescentis

MISSOURI BOTANICAL GARDEN

much more slender plant. than
the former for higher with
narrow leaves, shorter narrow buts
~~with~~ smaller flowerbuds (alabastri)
which are oblong lanceolate not obovate
and with narrow, linear petals.
I may be a variety of Ph. esculenta
In the neighborhood of Fort Gibson I find
it in flower by the middle of June
when Ph. esculenta, had ripe seeds!
in the Kickapoo prairie in South Missouri
it was not yet in flower by the last
days of May and Ph. esc. was past
flowering by two week. ——

198 Allium mutabile Mich. In open
woods, April. Houston.
This is Michaux's & Elliott's plant. and
it occurs ~~also with~~ with umbells
with a bulbous head, with or without some
flowers. The capsule is all one species
one seeded, as Elliott has it; capsula
trisperma of Spreng syst II, 37 is
certainly a mistake. — Usually red but we have also a white variety

I find in my Herbarium two Allia
collected by Gray — the one from Missouri
both are remarkable by the ovary
being crowned by six erect scales
(therefore angles of capsule 2 dentate above
as Mutt gen I, 215 has it); but
one has white oblong acuminate petals
and a reticulated bulb, and the other
red subacute petals and ~~bulbous~~ funiculated bulb.

195. Smilax lanceolata Lin (certainly Elliott! Pursh?)
July in rich shady soil near Water courses
Houston, climbing very high. The root
forms large tubers or knots, which
are called Indian bread in Texas.
The stem is armed below
Leaves ovate, but in the upper lanceolate
ones pointed narrowly
194. Pontederia lanceolata Nuttal
in British water on the coast near Pursh.
Lynnhaven & Hamilton July. ~~Probably only a variety of P. cordata~~

April & May. — ~~stem~~ 1½ feet
high; leaves ~~wings~~ pinnate, ~~lanceolate~~
2-3 pair on petiole, 5-6 inches
long 2 lines wide; spike 2-6 inches long,
twisted; parts with a ~~round~~ ovate gland
the germen flowers of the size of Spiranthes
cernua remarkable distinct by the
small lip, which is not ~~as~~ long as the petals, the
other segments of the perigonium —
which differs in this respect from
all the other species

Spiranthes cernua ♀ ~~stem~~ radix fasciculata
foliis vaginantibus. perigonii
segmenti lineari oblongis; labello ex ovato
oblongo, ~~obtuse lanceolato~~, acuto, ~~integerrimo~~ s.
pube ramulato
St Louis Sept & Octob.

Spiranthes ~~cylindracea~~ obtusa radice
fasciculata, caule foliato, foliis
vaginantibus, perigonii segmentis superioribus
ovatis obtusis. labello paule longiore
obovato ~~subunguiculato~~, obtuso crenulato.

Arkansas, ~~Octob~~ foliis nullis, caule
vaginato; Texas, foliis basilaribus
vaginantibus; fl. Octob. —
The Texas plant is ~~small~~ larger
and has ~~three~~ Leaves, more dwelling type
but the flowers are identical

Spiranthes tortilis (radicali) tuberu, uniro
(foliis radicalibus lineari bus) caule
vaginato. floribus, bracteis, cucullatis,
acuminatis ovariis subrecurvatis bus,
labello ~~lobato~~ obovato lobato i.
crenato.

Arkansas, rocky hills, Sept.

Spiranthes gracilis. radice fasciculata
foliis infimis ovato lanceolatis in petiol
attenuatis superioribus vaginaeformibus
basi ovato lanceolatis, acuminatis,

ovarium superum tubo cylindrico oblongo, ~~stamina~~ ornato, ~~filamenta~~, ~~stigmata~~ & ~~Antherae~~ Texas; ~~Sept. Oct.~~ Aug & Sept. Spec — for Texas all ~~May~~ for March to May; Dry Prairies Galveston & Houston — we can not distinguish it for the native form.

190 *Habenaria* auriculata. R sp.? radice tuberosa, tuberibus 2 ovoidis; ~~folium~~ foliis lanceolato-linearibus, elongatis superioribus setaceis; ~~spatha~~ germen tortum (non tortum) aequantibus; perigonii laciniis lateralibus extimis falcatis basi auriculatis, triangularibus, labio ~~simili~~, laciniis dilatis intimis, ~~oblongo~~ oblongo-linearibus, obtusis, calcare longissimo sursum curvato.

in Houston.

Mouth of Brazos, April — June

~~A remarkable species, perhaps~~ very remarkable on account of the ovary not being twisted & the open ~~therefore~~ upwards but the lip is hardly distinguishable from the two other, inner segments of the perianth. — The lateral outer segment have a large blunt tooth or auricle at their base, upwards so that they appear ~~form a one~~ triangular. the flowers bud ~~has~~ therefore ~~appears~~ gibbous upwards. Is it perhaps = Gymnadenia ?

189 Mora a

Open woods & Prairies from Houston to the Brazos — June & July — (also in Louisiana ?)

MISSOURI BOTANICAL GARDEN

Probably a Morrea ~~already described~~ it
is distinguished from Nemastylis under which
name I have received it from Louisiana
by the anthers ~~with thick~~ the cells are connects
by a broad membranous ~~[illegible]~~ and by the long style
(with three bifid stigmas) and by the ~~short~~ small
inner segments of perianth. — Nemastylis
has ~~style~~ segment equal with the three
convolute ~~often floating~~ sheathing petals /
and style short with 6 long segments of stigma.
I have it from Arkansas & Texas. —
Both plants without flowers are very
similar, but Nemastylis may be distinguished
by the membranaceous margin of the
long sheath of leaves and of the bracts;
Morrea has not that membranous
margin of the bracts and the stem-leaves
are nearly without sheath. —

I must remark however that I take to the Texan Plant there be the collection there is no tube or a very short one and the perianth segments are linear-lanceolate

187. Hypoxis erecta L. ~~Spec. Plant.~~
foliis planis, gramineis, scapo pauci-flora
~~duplo~~ longioribus, bracteis membranaceis, scariosis, perianthii segmentis
~~petalis~~ oblongis, ovato lanceolatis
acutis, exterioribus apice barbatis,
capsulis subglobosis perianthio persistente
basi tenue longe coronatis, seminibus
in loculis singulis biserialibus subsenis

β. australis foliis linearibus
scapum subæquantibus,

Common in dry clayey soil Missouri to Texas;
fl. in March till May. β. Texas in
Prairies which has been burnt in Spring.
fl. in July. — We have given the Characters
~~description~~ of the Species of Hypoxis
again, in order to distinguish it well
from the next species. The principal
difference we find in the short capsule
with 6 rows of seeds, the segment
it is usually smaller, has narrower leaves much smaller
and a shorter thicker bulb ~~of bracts~~ rounded
coming from bracts.

188 Hypoxis leptocarpa n. sp. foliis planis
graminieis, scapo pauciflora multo longioribus subulatis
bracteis omnibus s. superioribus solum scariosis, elongatis

perianthii segmenta petalis [illegible] *extus*
sparse pilosis; capsulis pedunculis
trigonis perianthium persistens sub-
aequantibus [illegible]; seminibus [illegible]
subglobosis.

In sandy soil along water courses
from to August — Buds similar
to those of H. heterophylla, covered with rough
dark hairs; but those as large
though the flower is only half the
size as the other. The fusiform corm
bulbs at the base of the stem
is in this species more elongated
and (probably on account of its growing
usually on steep margins of brooks)
~~roots~~ uncommonly horizontal, so the
the stem is ascending. The remains of
the bulb of last year are found on
the side (not at the base) of the new
bulb.

185. Xyris 4 Species are amongst Linnheimers
and I believe I can distinguish 4 others
among my specimens from the Southern States.
I will not attempt to describe all of them
to identify them. I do not know
which of the 2 have sent you.
I will however distinguish the 4 Texan species.

185. 1. Xyris from the Brazos, stem caespitous
edges very scabrous, denticulate; leaves
linear, grass like, long; bracts
obovate, slightly & irregularly crenulate
two lateral sepals acutish fimbriate and
irregularly incised; capsule obovate obtuse.
Spongy places in the Brazos west of the Brazos July.
If not named yet it ought to get the
name Xyris scabra.

186. 2. Xyris, to gether with the forgoing. —
stem many angled, handly compressed,
leaves linear setaceous much shorter
than the stem; however bracts obovate, narrowly
ciliate, two lateral sepals acuminate
subaristate, very slightly imbricate on the back,
capsule obovate. —
(Xyris angulosa H. & B.)

3. Xyris together with the two foregoing.
small (only 8 inches) stem compressed
but also striate or slightly multangular
leaves setaceous, short; head globose
bracts obovate slightly & irregularly crenulate

0 1 2 3 4 5 6 7 8 9 10

MISSOURI BOTANICAL GARDEN

Xyris spiralis

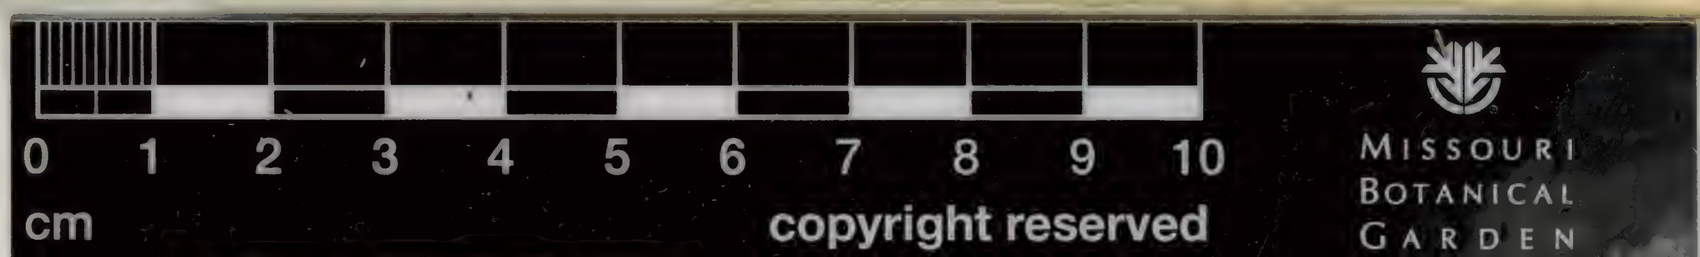
two lateral sepals subacute, fringed and keeled; capsule obovate obtuse. ——

4. Xyris Swamps near the Mouth of the Brazos. — September (also Alabama, the largest species, heads ½ inch long or more, — leaves broad, long — stem compressed two edged smooth leaves bluntly linear, long; heads oblong, finally cylindrical, bracts obovate, very entire; two lateral sepals acute, deeply & irregularly fringed & keeled. capsule emarginate obovate.. Xyris communis

184 Commelina angustifolia Mich
open woods, also in rich soil
grounds
Houston May.

182. Sagittaria lancifolia L?
grapo subamoso; basalis ovatis
acutis, subpubescentibus; ~~subtus~~
fl. femin. bracteis, fl. mascul. longe
pedunculatis; ~~obtuse basi~~ subcuneatis, ~~subtus~~ coriaceis
rostratis glaucis, alam, 20–30 ft
in ponds with Cayey soil near
Houston, June & September
Cayuga Sperry with broader leaves
183 and Cayuga flowers with 40–50 stamens
& British swamps, near the mouth
of Buffalo Bayou.

183, Sagittaria ~~subulifolia~~ latifolia n. sp.,
~~subulata~~ (radicante, stolonifera);
foliis submersis late linearibus
obtusis; emersis linear-lanceolatis
3–5 nervis; scapo simplici
bracteis ovatis acutis v. obtusiusculis
basi bus, pedunculis sublemis
omnibus elongatis, staminibus 12–16 v
superibus compressis oblique subobtusulatis
basi mucronatis.



Pontederia Houstonii, coll. = September (sterile flowering?)

I have also on sith bulbous radical, rigid leaves, coll. with
panicles. = March also sterile specimens? —

213. Eriocaulon prostratum n. sp. (culmis 4-11 cm. altis (annuus?)
prostrato, radiante ramoso;
foliis vaginis ore barbatis scabris pilosis
fasciculatis; capitulis 2 compositis, pedunculo capillari, ovata
spiculis brevi-pedicellatis, 12-12 floris;
glumis extensis ovatis acuminatis,
3 nerviis, pilosiusculis, interioribus
hyalinis, duplo longiore superante.

Sandy places. — th Brazos bottom July.

214. Eriocaulon radiatum n. sp. culmo (annuo?);
prostrato radiante, ramoso, foliis vaginis ore barbatis
pilosis, fasciculatis, capitulis compositis laxa, ovatis, spiculis
pedicellatis, 16-22 floris, glumis
exteriore acuto trinervio, nervis ciliatis
& scabriusculis, interioribus apice
hyalino laceratis, paulo superante.
Sandy places in th Brazos bottom
with th last species.

In th same locality was collected th nearly related
Eriocaulon reptans which in habit is
similar to E. radiatum but has
~~many flo~~ spikes with 18-26 flowers
and plants only half as large and thin
glume barely half th size of th outer one;
from E. prostratum it is distinguished by
th looser panicle by th smaller flowered
spikes much smaller florets by th outer glume acute,
(not long acuminate,) & th broader inner glume with two
more strongly ciliate nerves.

1 Lin. Th. Collect. 1844

Clematis fm Lackstry? without ticket, is near C. Virginiana, but appears distinct on account of the ovate acute not reflexed sepals, not acuminate, and the long tail of carpels, which are hardly pubescent: Clematis pitcheri? perhaps C. Pitcheri?

7. b. Cercidium Carolinium D C. female plants, in fruit, apparently more frequently than the male plant with habitually 3 lobed leaves. — On the Colorado river. October.

215. Brassica pilosa Punh = Clear rivulets = the prairies between Bravos & Colorado. Aug. July

8 Streptanthus hyacinthoides Hook, flowers nodding; siliques erect; our specimens mostly simple, with linear leaves, some lanceolate Cauline leaves branching, with lanceolate Cauline leaves Prairies between Bravos & Colorado April & May

Cheiranthus hesperidioides Torr. Shady damp woods, July — Ought to be examined again — perhaps a distinct species; no leaves hyrate, all simple, radical ones ovate obicular or cordate-obicular, —

216 Draba cuneifolia Nutt. Dry grassy places near Catsprings, west of the Bravos. March — Amongst our specimens we find some with nearly and others with entirely glabrous smooth siliculas. — This would indicate that Draba Caroliniana Walt and D. micrantha Nutt which differ only slightly = the pubescence of the siliculas are only varieties of the same species.

218 Nasturtium tanacetifolium Hook & Arn. Sandy open places in the Willowcreek-Cotton February & March. — Siliques incurved in some specimens nearly erect — others more patulous, — In some specimens collected in stonile places in the Prairies we find the leaves less divided simply pinnatifid.

It is very possible that this may be
one of the already described species, but
it appears to me to differ from all as
they are described. - Valg. Flor.
I would compare only V. grandiflora;
this has ~~V.~~ stellate pubescence green sessile
sepals, obovate petals, sagittate anthers
V. repanda has subulate filaments
V. angustifolia has stellate pubescence, and
leaves attenuated at base; V. Nuttallii
has leaves narrowed at base, and a distinct
silicle, V. gracilis has subulate filaments,
leaves narrowed at base, seeds not
marginate; & V. Shortii has very long
styles.

To the description of V. grandiflora I
would add from the ~~same~~ examination of
a single specimen; sepals green stellately
pubescent as the whole plant; anthers
sagittate with spreading lobes; leaves
sessile, somewhat dilated at base

231 Lupinus subcarnosus Hook

Growing from the base; from 6 to 15 inches high; flowers smaller, paler and inflorescence more silky or lanuginous than in the nearly related L. texensis Hook, of which we find a few specimens mixed with those of L. subc. — Prairies west of

2. Lindheimer Collect. 1846

Ft Bryan, Tex: April

232 Cassia chamaecristoides ♂ & ☿ ? nigrea Torr.

perhaps a distinct species; characterized not only by the characters noted in Torr's Fl. I p. 396, but also by the stipitate gland on the petiole below the lowest pair of leaflets; the setaceous glands between the 4- or 6 lowest pairs of leaflets (wanting in C. chamaecristoides) and by the indistinct (not very plain) veins of the acute (not obtuse) leaflets. The five alternate anthers are shorter. — Sandy places in the woods along the Colorado river. Aug.

233. Algarobia glandulosa T & Gr. — shrub or small tree, 6–8 inches thick & 10 feet high; low prairies on the Colorado. Fruit ripe end of August. This plant called Texas mesquit-tree in the Mexican tongue, is first found as a small shrub S. of the Nueces between the Bryan & Colorado, and becomes larger & more frequent in proportion as we advance westward, till it forms the mesquit thickets on the Colorado in the vicinity of the Rio Grande. Echinocactus (E. setigerus) is common on their border & the singular Opuntia camporadas (No 244); and on naked plains, especially on old prairie dog anthills a large Echinocactus (E. ringens, acanthodes) often a foot in diameter strikes the traveler with the impression of a tropical vegetation.

The leaflets are partly linear & obtuse, partly broader & elliptical, frequently 1/2 to 2 lines wide & 1/2 as long, but also obtuse & often as wide as long on the same specimen. — This plant is very remarkable on account of the drupaceous structure of the fruit; the inner part of the pericarp separates from the pulpy parenchyma, and encloses (separately for each seed) as many nuclei, as there are seeds. This structure appears to be found in only one more Tam. of Africa which however is unrecorded.

234 Silvaskia angustata Tall Sandy pinewds between Bruja & Colombo Mex to Aug.

57 Vachellia Farnesiana W & A. many of the Bruja. both woods, and sparsely in the Con prairies westward, and doubtless indigenous. — fl = March

235 Darlingtonia Cucullata bog globe S.C. y. flowers Tulip Wet Prairies west of the Bruja. fr = July. — We have also seen the slender var. illinoiensis from the seaward of Texas.

236 Prunus glandulosa Hook. ~~Prunus glandulosa Hook, Fl. Bor. Am.~~ I. gathered specimens as proved by a nearly ripe fruit, from one of our specimens; it is pubescent and dry; — Low, shrubby on rocky Hills in the Prairies west of the Bruja fl = ~~Feb~~. — Fruit yellowish red ~~of the size~~ & is large as a medium sized cherry (Lindheimer). — Drupe of one specimen = ~~half~~ grown fruit, entirely juiceless and still preserving the pubescence of the ovary

237. Prunus gracilis n. sp. ramis subteretibus; foliis oblongo-lanceolatis, infra saepeque acutis, grosse ~~irregulariter~~ serratis, ~~serraturis~~ plerumque patulibus, supra glabris, subtus ~~sparse~~ tomentoso-pubescentibus, petiolis brevibus, eglandulosis, stipulis setaceis glandulosis; petiolis, aequantibus, umbellis 2-3-floris, pedicellis calycibusque pubescentibus; calycis laciniis ovatis obtusis, disco patulis orbiculato, ovario glabro. — P. Pumila

In ~~part~~ open postoak woods (Quercus obtusiloba), ~~sometimes~~ in small groups (west of the Bruja, = fl = March. It is the Pr. Chicasa P. normalis of Torr. but I take it to be a distinct species characterized by the small (about 1/4 inch long)

was collected

This remarkable Cactus grows as stated above near the Th. Fork of Algarobia flat on the Colorado [illegible] August it acquires a height of from 3 to 5 feet, has a branchy ligneous stem, covered with a gray bark and sometimes even with lichens, and it bears bunches of small cylindrical like spines, with one larger one (about 4-6 lines long) which disappears on the oldest stem. The wood is very close grained, and hard. The young branches are green and angular and bear the last short (about ¼ inch long) articulations which break off very easily. Their spines, are white, with the obovate succulent fruits, which are fleshy, but not juicy, and contain very few (2-5) white compressed seeds. — The most remarkable circumstance however is that the fruits frequently bear one or more (even 4 or 5) new branches at the upper bunches of spines, either fall off with them or become fleshy persistent, dry up, and form part of the stem.

This species is apparently nearly allied to Opuntia fragilis Nutt., but is distinguished by the high ligneous stem, the mostly lateral position of the flowers on the branches, and the fleshy fruit.

Besides this Mr Lindheimer has sent us 7 other Cactaceae, most of the living specimens;

2. Opuntia without fruit and flower, probably O. vulgaris Mill. several feet high, with large obovate joints, from the Brazos.

3. Opuntia, perhaps O. missouriensis DC. low with smaller orbicular joints, numerous straight with large brown spines and brown bunches of prickles, which are longer than in the other species; flowers yellow; May. On sterile prairies 22 miles West of Houston.

× they bear when young as the other Opuntiae do, a fertile subulate leaves, and in their axilla the one larger spine and above this a bunch of small ones.

4. *Mammillaria* ~~caespitosa~~ ~~simplex~~ similis ♀ · radiis albidis spinosis at the apex of the tubercle, surrounded with a tomentum at their base, equal in size, spreading horizontally, ~~tomentosa~~ first axillis globis

~~caespitosa~~ Tuberculis ovatis apice spinigeris ~~spinis~~ radiantibus albidis pilosis sub lente pubescentibus, basi tomento ~~albis~~ circumdatis; floribus sparsis, baccis globosis scabratis. —

On Sandstone rocks near Industry, west of the Arroyos. — Evidently very near *M. simplex*, but caespitose forming tufts of 6 to 10 inches diameter, with white (not red) spines; flowers not seen. ~~about 12~~

5. *Mammillaria* ~~simplex~~ Haw subcaespitosa, tuberculis ovatis, apice subpolyspermo supra nodulosis spinis ~~subaequalibus~~ radiantibus, radialibus, centralibus, in plantis senioribus ~~4~~ centrali ~~subrecta~~ sub vix ~~floralibus~~ extrabilibus, fasciculatis ~~majore~~ fructibus ~~ovatis~~ (viresentibus) floris rudimentis coronatis

With the foregoing I would take it without hesitation for *M. simplex* Haw if that was not described as ~~with~~ having bearded tubercules! Ours are very spiny in the young ~~spines~~ we find 8 to 10 ~~radiating~~, horizontal spines ~~about equal~~ ~~but~~ much shorter than the old ones, one becomes central erect or with a little curve backwards and soft & long, flowers not seen; fruits ~~pinky~~ oblong, ~~juicy~~ green (about 10-12 lines long) in a cluster at the centre of the plant ~~tomentum~~ sessile surrounded by ~~tomentum~~ full of ~~seeds~~ black smooth shiny ~~ovate~~ seeds which are compressed on one side towards the hilum

6. *Echinocactus* ~~gemos~~ *setispinus* subglobosus apice retusus, costis plerumque 13 (15-18) acutis ~~subobliquis~~, areolis fasciculatis lanuginosis, flexuosis ~~ferrugineis~~ planiuscule fuscis 10-12 ~~radiantibus~~ inferioribus brevioribus, 3 superioribus 3-4 elongatis centralibus 1-3 longissimis ~~flavicante fuscis~~ arcuatis. floribus minutis ~~parvis~~ atropurpureis ~~ovatis~~ sepalis in tubum ~~longum~~ concretis apice ~~liberis~~ ~~et~~ laciniis late ovatis acuminatis margine ~~laceris~~ ~~ciliatis~~ fimbriatis ~~ciliatis~~ fructibus ? seminibus ~~nigris~~ ~~ovatis~~

(~~ovatis~~ ~~oblongis~~ ~~tomentosis~~)

oparis mianti tuberculatis.

(common amongst the Mesquit-trees (№ 233) on the Colorado river. – Near Echin. tenuispinus Link & Otto, & Brasilicus Kth. distinguished by the somewhat oblique & acute, not ~~straight~~ obtuse ribs which show at their bases a ~~tubercular structure~~ transition to the structure of the ~~tubercles~~ Mammillaria; – also by the very small flowers. – Our specimens are about 2 inches wide and 1 1/2 inch high; have 13 ~~rarely 12~~ (out of the 15) pretty sharp ribs, separated by deep grooves the spines near the base are short mostly broken off towards the top they are long-flexible those in the centre are the longest (about 15 lines long) ~~the flowers do not open for the cluster~~ (We find a few shriveled up flowers and one whole plate fruit on our specimens; they do not originate from the clusters of spines but from an impression in the rib above them. The flowers are small, about 5 lines long, pale ~~yellow~~ surrounded by a tomentum; the seeds are punctulate black, not shining. –

7. Echinocactus? ~~Gregii~~ gyracanthus

~~subglobosus~~, vertice ~~apice~~ depresso, costis 21 ~~rarius~~ verticalibus, acutis, subundulatis, aculeis ~~e tuberculis~~ ~~forticulatis~~, ~~inaequalibus~~ ~~6-7 extensionibus inaequalibus subulatis~~, compressis transversim striatis, ~~cinereo rubellis~~ 6-7 extensionibus inaequalibus subulatis, centrali multo longiore, recurvo; floribus ?

On ~~naked~~ old anthills near the Colorado river, "often a foot in diameter." – Our specimens are 8 or 9 inches ~~wide~~ in diameter and 4 or 5 inches high, none of the flower, nor fruit we a notice of flowers or fruit in the letters. – Evidently near E. viridescens Nutt. from California with which it has the habit or assemblage of spines in common ~~tuberculis~~ previously

depresso-stellato-lanuginosa

ex areola tomentosa

also near E. Cornigerus Hr. platy acanthus Link & Otto who say nothing however of the annulate spines, nor do they indicate it in their figure. The shape of our species however is different from any other we find described it is only half as high as broad and resembles that report melocactus placentiformis. If really all the Echinocacti have smooth spines, our species naturally [illegible] easily distinguished from them by their annulated ones spines;

by their shape E. viridescens being higher than broad and by the spines of which the shortest are straight; our Echinocereus may be known by its depressed shape (E. viridescens being higher than broad) and by its recurved spines, of which the shortest ones measure 10.–15 lines, and the longest ones as much as two inches. Some of the older spines we find covered with lichens.

8. Cereus? caespitosus

ovato globosus, costis 15 angulatis, areolis [illegible] laxe lanatis, radiatis (inaequalibus) longioribus, lateralibus majoribus

Growing with near Cat spring, west of San Felipe. — A singular plant, probably a Cereus of reduced dimensions, and near C. radiatus DC or the smallest Echinocactus, and of the simplest growth? — The heads are 1 to 2 inches in diameter and a little higher; among our specimens are some growing out of the side of another one and others growing out of its top — Opuntia-like! We find (mostly 15 ribs and also occasionally 12 to 17) ribs, which are formed by confluent tubercles each of which bears on top a bunch of about 20 to 26 radiating spines of 1 to 2 lines long. Spines not seen but flowers apparently originating between two clusters of spines and at base surrounded by long wool

costis 15, tuberculis concretis, areolis laxe lanatis, radiatis (inaequalibus) longioribus

sub-15 costis tuberculis concretis, areolis laxe lanatis, radiatis (inaequalibus) longioribus

× spine depressed umbilicated

× longest on the side and curved backward

4. Lindheimer Collect. 1844

Besides these 8 species we find in Mrs Lindheimers letters a mention made of a 9th species a small curious wiry angled Cactus on the siliceous hills near La Grange. But we do not find specimens in this collection.

245 Sedum spathulifolium Hutt. Rocky sandy spots in the San Bernardo Prairie between Brazos & Colorado. April & May.

246 Galium virgatum Nutt. Prairies west of the Brazos; in patches. April.

247. Diodia teres Walt. Swamps in low fertile places of the Prairie 16 miles west of San Felipe. June. — The plant is much branched, spreading resembling in habit Hedyotis Boscii &c. All specimens also examined by us also triarrhellary.

248. Cocculus laxus DC. Shady thickets along Millcreek west of San Felipe. July.

80 Gaura coccinea Nutt. Dry prairies between the Brazos & Colorado. Sept & Octob.

83. Oenothera speciosa Nutt. Open Places in the Prairies west of the Brazos. Sept.

94 Echinacea angustifolia DC. In clayey Prairies west of San Felipe. April & May

96 Helianthus cucumerifolius Torr & Gray. Sandy soil west of the Brazos, May & Sept.

We have this and the nearly related H. praecox (No. 97.) and find them very distinct; besides the characters enumerated above — we find the leaves of H. cucumerifolius constantly toothed; of a deep green colour; the involucral scales long; with subulate tips at first erect, not covering the disc before the opening of the flowers, afterwards gradually reflexed. The flowers with a very short tube and long wide neck. H. praecox has rarely toothed leaves. The leaves of the mostly abruptly abruptly alternate into the petiole, more or less toothed, sometimes very slightly

in oth spermens. disperse but never sessile
of a pale somewhat cinereous hue.
involucral scales lanceolate acuminate
adpressed, covering the disc flowers before
flowering. corolla of disc flowers with a
long tube & short neck, therefore the
disc flowers much smaller than
in the foregoing species, & nearly ~~upright~~ flat
in the other it is hemispherical. — Achenia
considerably smaller. — It flowered
in our North Climate the same time
as its relative, pro- June to October
in its native place (Galveston in Texas)
It probably is a semi biennial plant &
germinates in the fall & comes to
flower as early as April.

104 Gaillardia amblyodon Gray. in light sandy
soil west of the Rio Grande; May to July.
Rays bright red, brownish purple at base.

107. Hymenopappus artemisiaefolius DC.
Sandy soil open bushes near
the millcreek (Mexican) 16 miles east of San Felipe
in flower from March to September. One specimen
still. ÷ March. Lowest leaves entire
or lyrate or pinnatifid ~~never bipinnatifid~~
with entire or even with irregularly toothed lobes
growing sparsely

110 Marshallia caespitosa Nutt ~~singly~~
on dry prairies near the Millcreek. April.
Lowest leaves spathulate, oblong 3 nerved
large, broadly ovate
acuminate but otherwise not differing
from the common form as described by

Stems 12 to 15 inches high

Pterocaulon leptostachyum n. sp.; caule herbaceo
ramoso, foliis superioribus lanceolatis supra sericeis
lineatis — omnibus undulato dentriculatis
supra glabris, subtus albo tomentosis, capitulis
fasciculatis; capitulorum sessilibus in
spicam elongatam interruptam congestis;
involucri squamis ~~exterioribus~~ abtis exterioribus lanceolatis brevibus
dorso tomentosis, interioribus linearibus elongatis, apice glabris
glabris subulatis

Open Pine woods near Houston, fl. Septemb.
— Apparently very Easily distinguished from
the only other N. American species P. pycnostachyum;
by the ~~Co~~ branching stem linear leaves,
interrupted spike etc. — but perhaps
to near P. interruptum DC from
Brazil; but apparently distinguished by the
narrow undulate-dentriculate leaves, short involucre

0 1 2 3 4 5 6 7 8 9 10 cm

MISSOURI BOTANICAL GARDEN

are described as oblong-lanceolate, irregularly dentate. — The sp. A. ~~sp.~~ A. spicata are from 2 ft to 3 feet high, more or less branched, slender, interrupted spikes 4 to 7 inches long, ~~composed of~~ glomerules ~~of~~ enveloping the spike from 6 below by 3 to 5 or 8 heads above the lowest are sometimes single, pistillate flowers numerous in many series, perfect ones 2 to 4 in the centre

mostly sessile but in one or two instances we found the lowest ones pedicellate

257. S. Elphinstonia Hook. Shady woods west of the Bravos, May to July. — ~~Arkansas~~ Broadly winged somewhat ~~pubescent~~ obconic or oblanceolate obtuse thickly scales adhering to the base of the bony wing, somewhat pubescent achenia.

258. Helianthus Lindheimeri Torr & Gr in Sandy open Post Oakwoods west of the Bravos, May to August. — From a large perennial rather fleshy root rise many stems 2 to 5 feet high branchy above. lower leaves rhombic-ovate or ovate lanceolate acute tapering into a petiole of nearly their own length, or shorter a little higher up the bases of the petioles widened, and clasping, as in H. Elphinstonia perfoliatum, and the upper leaves are entirely ~~sessile~~ perfoliate, without any show of petioles. — Exterior involucre of all spreading & partly, ~~strongly~~ foliaceous scales rhombic-oval acute on the margin and the inner side ciliate — pubescent. Ray ~~as well as disc~~ flowers with a hairy tube (not only involute); tube of disc flowers otherwise hairy.

259 Helianthus Cutleri Torr & Gr In low shady woods and on wet prairies between the Bravos & Colorado. July to Sept. — In the former it is lower but in the latter woods it attains the height of 10 and 12 feet. the lower leaves ~~have petioles of~~ are oft 6-9 inches long and 5 to 8 inches broad and have petioles of 6-8 inches length; flowers 2½ to 3½ inches diameter; achenia oval, thicken

the usually in the Genus.

209. Helianthus asperrimus n. sp. perennis, hispida
caule erecto simplici, foliis alternis (v. oppositis)
lanceolatis subsessilibus integris, penni-
nerviis, rigidis, supra capitulis asperrimis, subtus
planibus; axillis foliorum superiorum
breviter pedunculatis; involucri squamis
lanceolato-linearibus acuminatis apice squarrosis,
receptaculi hispidis; floribus radiis 18-21
glabris, disci pubescentibus; achenii
glabris, squamis pappi 2 lanceolato-subulatis elongatis
lanceolato-subulatis, fimbriatis.

Covering large patches of the prairies
between Bayous & Colorado. October.
— Near H. gigantea but easily
distinguished by its great roughness, low
growth, simple stem etc. ½ The simple stem
rises from a thickened rhizome 2 to 3 or 3½ feet
high, in the flowering plant naked below
the corymbose panicle of flowering heads;
leaves sessile, the lowest ones 4 to 6 inches
long, the upper ones gradually smaller,
all rigid, very rough-asperous, dull green,
3-nerved, the lowest ones lanceolate, the
upper ones linear-lanceolate, all entire
or the lowest ones sometimes slightly
denticulate, the lowest ones sometimes
opposite, the upper ones alternate;
involucre hemispheric, 12 lines high,
of numerous (about 30) unequal
rigid, very rough-asperous, dull green,
lanceolate-linear, acuminate, spreading
or squarrous, ciliate-fimbriate scales;
receptacle pubescent; rays 18 to 21,
yellow, 15 lines long, 4 lines wide;
disc-flowers numerous, yellow, pubescent
especially near the throat; proper tube short,
achenia (immature) glabrous, 2 lanceolate-subulate
chaffy fimbriate scales of 1 line in length.

½ Also near H. grandiflorus T. & G. but apparently
distinguished by the more or less
squarrous involucre, by the narrower
lanceolate, not ovate-oblong leaves,
by the very scabrous covering of the leaves,
feathery veins, not triplinerved leaves
and by the globrous achenia. — Perhaps too near H. Mexicanus Gray but
distinguished by its low growth
simple stem, more lanceolate
rather broader and less
squarrous scales of involucre

N. Artes Drum
& grex

260 Helianthus Maximiliani Schrad. Prairies,
margins of woods, along fences and in
deserted fields, Ills. Patches together
from Houston to the Colorado R.
Oct & November, the latest flowering
species in Texas. × Our specimens
from Houston have slightly scabrous
stems. There from the Brazos are
sensibly scabrous. Chaff mostly entire
abruptly acuminate or at the apex jaggedly
rarely with two very small lateral teeth.
The lowest leaves are slightly petioled
but attenuate & long acuminate
very slightly repandly denticulate; equally scabrous
on both sides

× grows 4 to 7 feet high, much branched

262. Helianthus grosse-serratus Mart & A. Sentry
Branches of rootstock and margins of
woods. Aug to Oct. — This appears to be the
original form of this very variable species
with oblanceolate base
leaves coarsely serrate, with divaricate
teeth, tomentose on the lower side
silky. — The involucral scales, are
chaff very soft
mostly entire (but not abruptly acuminate)
The receptacle of the disc flowers
very profusely with a middle nerve
stem very smooth & glaucous
somewhat but smooth, as many nerved.
New St Louis we have several other forms
with opposite, & alternate leaves,
ill tomentose below or only slightly
canescent with strongly ciliate scales
or nearly smooth
of the involucre. but all have leaves
with a very acute base and slightly
and appressed serratures and narrower
mostly only 3 nerved involucral scales

263. Helianthus grosse serratus Mart. Boreborior?
This variety was collected with H. Maximiliani
and the specimens of both were mixed
They are readily distinguished however
by the all the leaves being petioled
and more canescent the scabrous on
the lower surface, and appressed serrate
(or nearly entire); they are very acute
at base, and the stems &, though
somewhat glaucous, are somewhat scabrous
slightly thought.

MISSOURI BOTANICAL GARDEN

the lower leaves ~~f~~ which were ~~found~~ with
this ~~H. Maximiliana~~ evidently belong to
this species; they are petiolate, ~~smooth~~
abruptly acute, serrate ~~and~~ rough
on the lower surface

Perhaps the H. Maximiliana, asperrima, ~~H.~~ H. gracilis
and grosse-serrata are very near
each other; ~~H~~ H. grosse-serrata is distinguished
by the petiolate leaves (which are only sometimes rarely coarsely serrate..!)
smooth or slightly scabrous ~~stem~~ stem or pilose
~~H~~ gracilis by the hirsute stem & leaves
~~H~~ Maximiliana and ~~H~~ asperrima by the sub-
-sessile leaves which are scabrous and
equally green on both sides, — The genus
Helianthus is one of the most difficult
of all those for ~~D~~ D. Amerika as
we can hardly rely on any one
constant character, they ~~are~~ all more
or less variable and ~~there~~ are intermediate
forms which apparently connect the
most distinct species. —

264 Cosmidium filifolium Torr & Gr. ; Prairies
west of the Brazos. ♃. May & June. —
A perennial plant!

265 — Dysodia tagetoides Torr & Gr. ~~Lake~~ Prairies
near springs on the declivities of the Lookout
on the Millcreek. August. — ~~Perennial~~ Stems of the
leaves orange yellow.

266. Palafoxia Hookeriana Torr & Gr. In sandy
Postoak woods, ~~in~~ fruiting, ~~flowering~~
fl. in August. — This as well as P. texana &c
are annuals!

267 Actinella linearifolia Torr & Gr. On the
declivities of Sinclair hill near Industry.
May & June. — Rays yellow, turning
white when fading.

268. Venegia amplexicaulis Hook. annua (? v. biennis?)
glaberrima v. floccosa, caule ~~stricto~~ erecto fistuloso
~~striato~~ supra ramoso, foliis caulinis
ovato-spathulatis in petiolum decurrentibus

In th Prairies, between Brazos & Colorado
& on wet places, β on the Austin
Coast sandy soil of th
deserted and hilly togeth with Aycemore
mexicana. — 14 — April. —
This we have no doubt is Hookers
S. angustifolia, though it certainly
is an annual or biennial plant &
is numerous specimens collected with
roots prove. — We can not sufficiently
distinguish both forms, the the
glabrous variety grows in wet soil, is much
more slender with narrower leaves
sometimes, etc; on a few specimens
we can observe a remnant of
floccolency; the variety from
dry places is a much stouter
plant with broader, thicker leaves
of a darker green color, but frequ
with a tint colour, whole plant more
or less floccolent; — flowers about 50 or 60
in each head.

269 Linum [illegible]

270 Lygodesmia aphylla DC. B. Texana Torr & Gr.
Prairies, Mayis of woods, west of th
Brazos, June, July. — Root penetrating
deeply into th soil, fusiform elongated tubers.

but on the side of the leaves, flowers very large
ately about 5 lines long, & ca 6 or 7 lines
of the same length and nearly three times
as long as very slightly stipitate at base suddenly x
the point, and doubled,
but not tubulous; when expanded
they appear three lobed, undulate lobes
crenulate rounded lateral ones shorter
acutish; — but the two horns double
the inner shorter one erect, included
the longer one exserted curved inwards
and nearly horizontally, both horns together
with the inside of the cucullus undulately
pubescent; — as far as included x
membranaceous, obtuse, erect.
the fleshy
ovate caroled, longacuminate
pubescent 8-angled angles
of the somewhat tuberculated exterior
one with soft spines or a dentated
carina (Lindl.). — the fine
opening with nearly ripe fruit
below and open flowers above
without intermediate buds of the same
green fruits, so that the plant
appears to flowers at different
times during the season. —
Very well distinguished from any of the
northamerican species but near
A Conjoinum Both from Mexico
— in fact according to the descript
&c. books we can not find any
other difference but the shorter cucullus
and the roundish ovate pale caruncle fully
with the two horns is not
said, nor with the cucullus an regularly
3 lobed. —

Sullivant n. sp.
Asclepias glaberrima, St Louis; misc
Asclepiadaceae

x The only other Asclepias with a bifurcate horn known to us is A obtusifolia Mich. both prongs are slightly exserted there though the inner one is so as in our case shorter than the other;

x very narrow about the middle

x only x pubescent one third of the length of the petals;

7 Linnaean Collect. 1844

273. Gondolobus ? ~~cuneiformis~~ cymarchoides n. sp.

caulibus plumbeis basi ramosis adscendentibus s. prostratis hispido-
~~pubescentibus~~ pilis ovatis (ovati)
acutis rubris brevibus petiolatis,
utrinque pubescentibus pedunculis brevissimis
floribus geminis pedicellis basi bracteis subulatis
suffultis petiolo plerumque longioribus
calycis hispuli lobis ovatis acutis
corollae luteae ovatis obtusis extrorsum
pubescentibus introrsum glebris (ex viridi
purpureis); corona staminea cyathiformi
gynostegii basin cingente 5 loba, lobis
(crassiusculis, rotundatis), margine ciliatis
supra processu linearis scapiformi
coronato ornatis; folliculis ovatis utrinque
attenuatis corneis ~~spinosis~~ muricatis
pubescentibus, seminibus nudis
obovatis marginatis, comosis.

Gondolobus ~~pedicellatus~~ pedicellatus (n. sp.) near
Ruiz et Pav. — This is apparently
to be on one side nearly related
with Lachnostoma prostratum Dne on the other
still nearer with Chthamalia Cuspidata Dne.
But the very peculiar structure of the corona
staminea might characterize it as a
peculiar genus if it should be settled
that any diversity of form of this organ
among the wonderful constitute a generic
difference in this family; — But the
Decandolleans himself the monographer of this family
in DeCandolle Prodromus appears to have
no settled views or he could not have included
Gondolobus hirsutus Mx and G. macrophyllus Mx
with this campanulate corona with 5 bigeminate
and 5 short broader teeth with in the same
genus with Gondolobus lobatus Mx in his genus
Gondolobus corona staminea — annuliformis
lobis integris". — We are therefore of the
opinion that not only our plant ought
to be referred also to Gondolobus but have
little doubt that more species of the
genus Chthamalia, too (probably the North american ones)

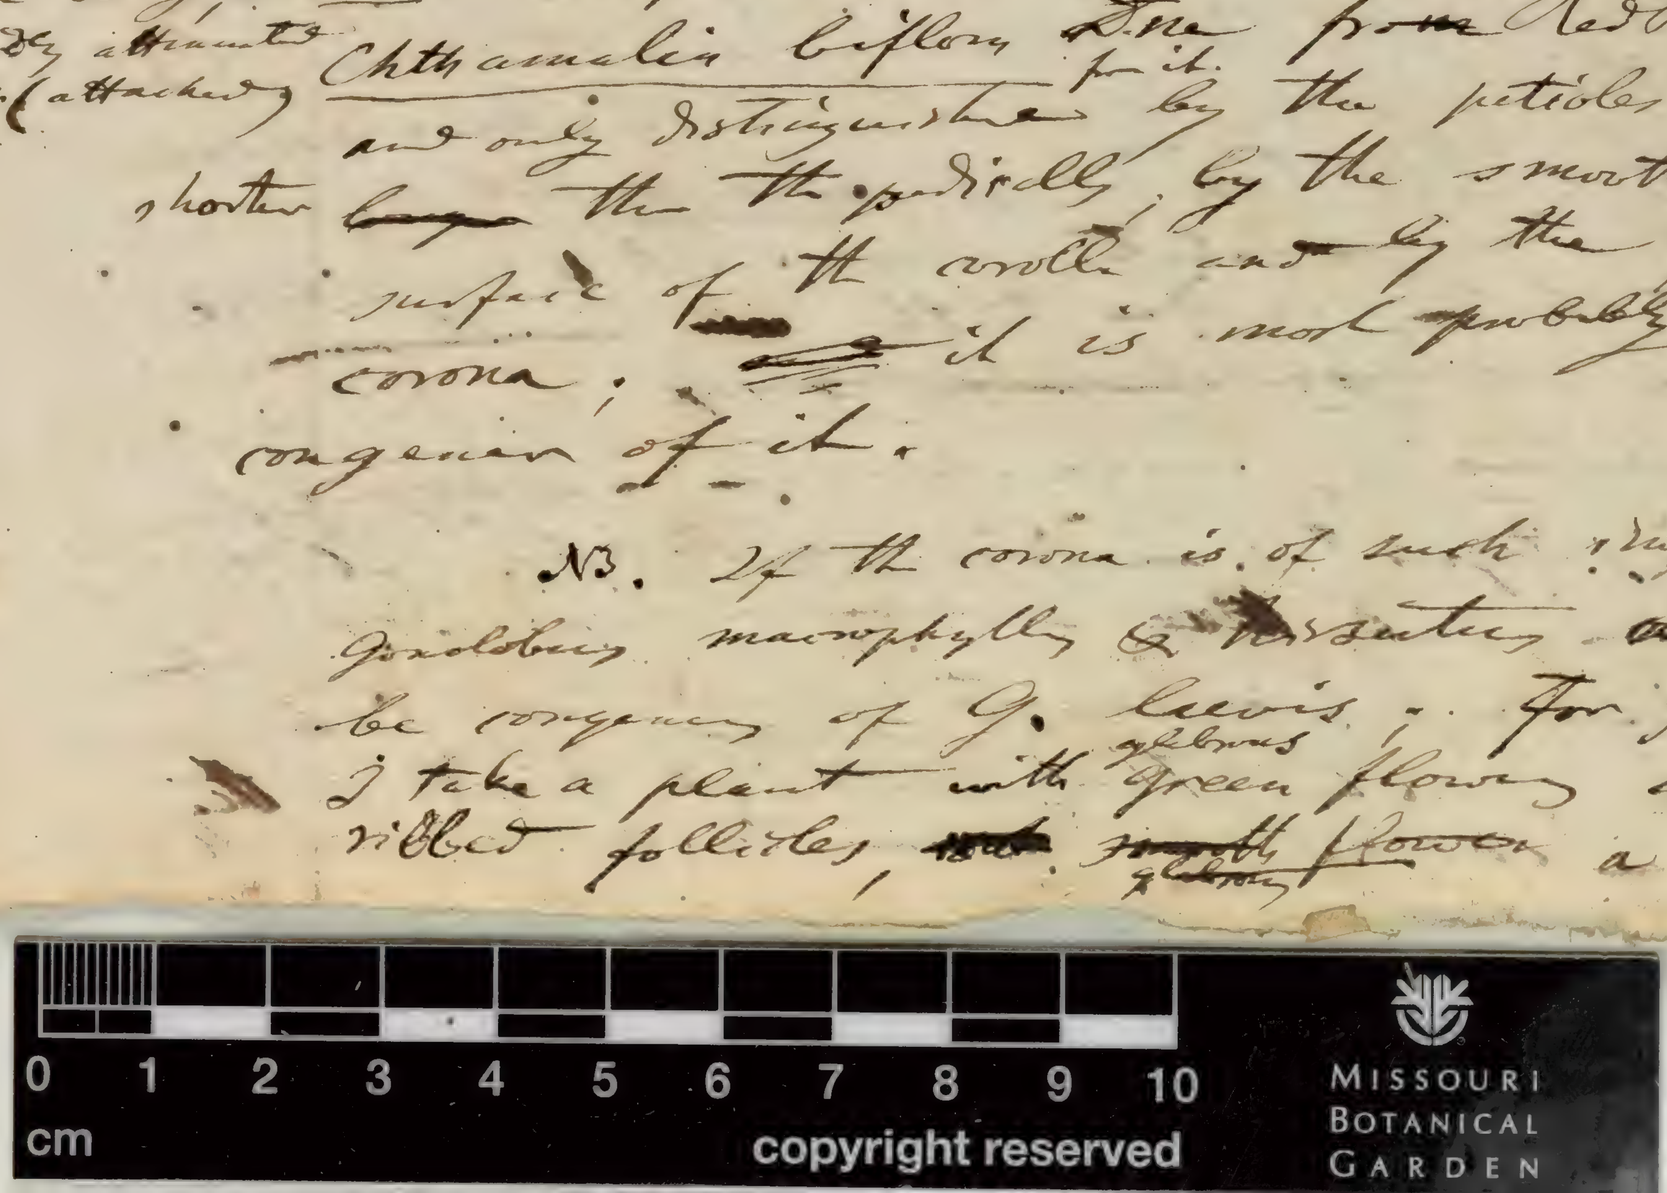
must be restored to Goldbea.

Our plant ~~plant~~ ~~and~~ is a perennial somewhat tuberous root mostly several weak stems, 6 to 15 inches high branching at base, ascending or ~~ap~~ prostrate; ~~the~~ leaves opposite cordate, with an open sinus 1 to 2 inches long on ½ to 1½ inch ~~long~~ or very short petioles 2 to 4 lines long, upper most leaves smaller nearly sessile ovate lanceolate, ~~the~~ more ~~than~~ often cordate at base ~~the lower~~ flowering ~~mostly~~ towards the top of the stem in ~~bunches~~ ~~and the~~ with pedicells longer than the petioles, only where they occur lower down the stem the pedicells are occasionally shorter the pedicells. There is a common peduncle sometimes a line ~~long~~ but mostly only half that length, always bearing two pedicels with two subulate bracts at base. The greenish purple corolla is very slightly hairy ~~outside~~ & perfectly smooth inside. The corona is ~~upstanding~~ frilled. the lobes (fleshy rounded) with a thin membranous margin and in the middle with an incurved process which ~~is~~ nearly reminds us of an Asclepiad, this process is connected with the middle part of the anthers and is free and incurved at the ~~the~~ apex where it is truncate somewhat like a spoon or ~~the~~ its upper surface; the ~~the~~ stigma of the very ~~slender~~ slenderly ~~an~~ angular stigma. The ~~extremely~~ minute hairy pellucid masses are ~~only~~ mostly arranged at their ~~exterior~~ (attached) end

Chthamalia bifloria D.C. The plant appears to be very near from Red River and only distinguished for it by the petioles being shorter than the pedicels, by the smooth shiner surface of the corolla and by the peculiar corona; it is not probably a congener of it.

N3. If the corona is of such importance Goldbea macrophylla & Nuttalliana not be congeners of G. laevis; for G. laevis I take a plant with glabrous green flowers and ribbed follicles, ~~with~~ smooth flowers a very



small individually 5 lobed staminal corona
and 5 fleshy projections of the centre of the
tube, under the very narrow membranous
crisp or ciliate margin. — This is probably
the I have specimens of this from Arkansas
Louisiana & Texas; mostly with ante
or very shortly arcuate ascending but also with
attenuate arcuate leaves and sometimes
even with something like pandurifom
leaves. — It is probably the same as
Nuttalls G. viridiflorus (G. Nuttallii Dne).
what is G. tuberosus L Sir?

I dont like Decaisne entirely
why Arenaria to Jussieu Hedysarum?
why Astragalus pauculatus (for Hedysarum
to Atkins & Texas,) an Arenaria;
why Otonia a subgenus of Hedysarum;
Linn. true Hedysarum have biarticulate
(coiled) and not a few have the
longer than the gynostegium!

MISSOURI BOTANICAL GARDEN

J. Lindleyanus Collett. 1846

A small
stem about 1 foot high, erect, acutely quadrangular,
branchy above, glabrous; leaves
opposite oblique, alternated into the petiole
slightly serrate upper ones half clasping
below with a narrow above with a broad base
acute acutely & unequally serrate two inches
& more long, about 6 lines wide
inflorescence pubescent. flowers opposite or
short pedicells forming a spike
2-lipped upper lip with 3 short, roundish
abruptly subspinulose lobes lower ~~lip~~ lip
flowers are thrown back, lower lip
with 2 lanceolate acute lobes which
after flowering the upper lip is
thrown back at lip and the lower incurved
so as gaily to close the interior
approaching the true Scutellarineae
Corolla about 5 lines long upper lobe
apparently flesh colour with a yellow
throat upper lip (entire erect retuse
much shorter than the lower lip
which is three lobed lobes horizontal, middle one
broadest emarginate or slightly 2 lobed
lateral ones entire; (corolla mouth inside
bent stamens hairy at the middle to sheath
please the upper shorter ones are adhering
to the corolla; anthers purplish, mouth
bent with short white, or teeth at the
sides ~~of~~ is apparently
intermediate between Scutellarineae
and Melissineae but nearer the
first on account of the shape of the
calyx in flower & fruit.

287 Brazoria annua n. sp.

Brazoria n. gen. calyx campanulate
5 additional nervous reticulated bilabiate
labio superiore truncato breviter 3 lobo lobis truncatis
inferiore breviter bilobo lobis 2 lobis lobis rejectis
lobis omnibus denticulatis; corolla
tubus longe exsertus; intus prope basin
pilosa annulatus, subtus inflatus palatum
inferiore expanse sub fauce
concava superna intus palatum referente
labio bilobato undique crenulato labium
superius (bilobum galeatum), inferius,

horizontale tri-lobum, lobis bifidis. Stamina 4 inferiora longiora, filamento sub galea inclusa, filamento supra medium villosa adnata ubi pilosa incrassata, antheris didymis, oblongis, stylus glaber, apice bifidus, lobis brevibus acutis, achenia [illegible] acute tetragonia, [illegible] pubescentia.

Herba annua texana ramosa pubescens foliis glabriusculis, caule dentato-sulcato, ramis divaricatis. Nom. a loco natali ad flumina Brazos.

Brazoria annua ☉. ♃. — Or

Dejected anthills with Argemone mexicana Datropha stimulosa, Helianthus annuus, Phlox Drummondii etc. — Stem, several branching from the base, simple or pubescent; leaves nearly smooth, obovate, obtuse, attenuate into a petiole, above sessile obovate-lanceolate acute, upper ones all irregularly dentate-sulcate; bracts very shortly pedicelled, hairy, ovate acute nearly as long as the calyx, nearly 2 lines long and as wide, closed in fruit, with the upper lip rounded, rolled in pale rose colored, with yellow dots, about 4 lines long; tube below the lower lip thrust inwardly so as to form a prominent palate inside; upper lip with two acute lobes, lower one with 3 obtuse ones which are again deeply emarginate — 2 Stamens. Stalks especially the lower (acute) ones remarkably thick especially in proportion to the small anthers, connected with the corolla for more than half the length and hairy at their base, perforate near the base of the corolla and again above, where the detach themselves from the tube. — The genus is

acquabilis

† ad Sordellam proxima accedens.

× 2–3 lines long by 6–8 lines wide

× spike compact elongated

very near Trinidad. but distinguished by the shape of the calyx lips of which are lobed and whit is entirely pentafid and by the corolla with its angular palate which resembles much the palate of — Utricularia some persontate.

28.5 Hedeoma citriodora sufft. suffruticosa, ramosissima viridis pilis crispulis pubenula foliis breve petiolatis oblongo — lanceolatis integris s. versus apicem dentículatis — axillis foliorum dui 3 floris — pedunculis tubuloso ovatis, calyce labio superiore dentibus 3 lanceolatis, inferioris 2 subulatis longioribus, corolla tubo longe exserto, limbi labio superiori emarginato, inferiore majore 3 lobo medio dilatato bifido; nucamentis oblongis. —

On Sandstone rocks near Inchetuy July: — The whole plant has a strong taste and smell of lemon peal, — stout numerous 8–12 inches high, somewhat pubescent 4–6 lines long, lines wide, or with a little reburn, veined and dotted; flowers calyx 2 lips very unequal, but all the lobes lanceolate; corolla long exserted about 6 lines long.

288 Physostegia dilatata nsp erecta, glaberrima, inflorescentia minutissime pubescente; foliis infimis oblongo lanceolatis obtusis integris s. repando dentículatis in petiolum attenuatis, caulinis e basi dilatata cordata sessilibus augustatis, a basi serratis dentatis serratis, superioribus obtusis acute serratis, summis integris; spicis elongatis, remotiflores, glomeris 12 floris, calycis dentibus triangularibus subaequalibus. — —

Wet prairie west of San Felipe, in patches together H. ∴ April.

both appear to be congeners. Gendarussa Nees ? but 4 stam. Beloperone ?

Calyx indistinctly 2 lipped upper lip 3-, under lip 2 parted segments nearly equal; ~~upper lip of~~ tube of corolla (inside woolly) ~~on the lower part~~ below the lower lip; upper lip bilobed, reflexed, lower lip deeply 3 lobed lateral lobes horizontally divaricate calls of the anthers distinct, one above the other, stigma acute, simple

(gynogynum 7 & May.)

NB. No 157 is congener of Ruellia strepens, Dizygandra Meisn capsula pubescente, 10-12 sperma, well distinguished by the pubescent, ~~astigmate~~ calyx by the glabrous and the pubescent not smooth capsule, also more seeds (8-12). — Dizygandra appears to be distinct from Ruellia or Calophanes (the N. Amer. Ruellias) by the bifid stigma and the large number of ovules. Ours has a strong dilatation — & denticulate auction (like true Ruellias) & does it connect again Ruellia Dizygandra & Calophanes ?

Stamina connate per pairs = 4057 = 4058 - 4060

Dizyg. strep. fil. com. basi hirsuta per pairs connata
D. undiflora, fil. basi glabra per pairs connata

I come to the conclusion that the genera of Ruellieae are by far too much split nearly every one of our species must form a distinct genus if we follow the plan of Nees. Calophanes, separated from Ruellia comprises most of the north american genera; Ruellia strepens has been separated as Dizygandra Meisn; our Ruellia undiflora No 157 is near this and perhaps ought to be referred to it but it has not a bifid stigma but a ~~bifid~~ subulate simple one; in other stigma with a small tooth at base like the true Ruellia; ~~the~~ capsule contains 8 to 12 seeds.

~~Here we not unite it with Dizyg.~~ the filaments are similar to those of Dizygandra connected by pairs at base. — If we can not refer it to this genus on account of its dioecism

but only at

× the ~~stamens~~ anthers are conspicuate at base — the stigma

---

158 Calophanes v. Cosmos if we adopt Don's new genera; but here we get into great difficulties, and have to make several new genera! Dizygandra has already been separated by Meissner and ought No 157 ought then to constitute a third genus: as my diagnosis (sent last year) is incomplete I send a better one here

157 Riellia Collyen Paniculata ? only × quinquefida, subaequalis, corolla tubo cylindrico, infundibuliformi — Stamina 5 fertilia, subaequalia; quinque filamenta plana petaliformia; staminodia 4 corolla faucem inserta, filamenta 4 connata; antherae 2 circulares, loculis lineáribus parallelis, basi cuspidatis; germen 2 circulare, gemmulis plurimis; stylus simplex stigma simplex subulatum; capsula ~~subcompressa~~ lanceolata attenuata, 2 cornuta, 8–12 sperma, semina orbiculata compressa, retinaculis subtensa

subulatus

Paniculata nudiflora; distinguished from Dizygandra by the entire stigma and capsule from Calophanes by the larger number of seeds. — Easily distinguished from all by the paniculate flowers, and the pubescent (not hairy) filaments with are not so much connected at base.

and conspicuate anthers

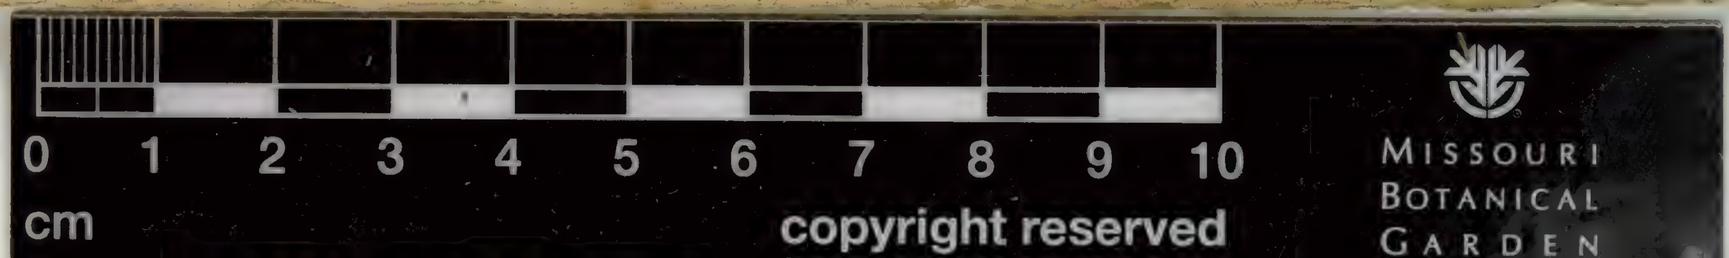
290 - Dipteracanthus micranthus n sp.

Mesophanes subgen n. gen. calyx 5 partite, subregularis, corolla hypogyna tubulosa, limbo quinquefido subregulari (erecto?), stamina 4 corollae tubo inserta, inclusa didynama, filamentis pro parte basi in ejus connata, antheris bilocularibus loculis parallelis muticis; Ovarium biloculare loculis 4 ovulatis; stylus simplex; stigma subulatum basi dente aucto (s. inaequaliter bifido); capsula bilocularis 8 sperma loculis bivalvis, valvis medio septiferis, semin orbiculata compressa, retinaculis uncinatis sublensa.

Herba mississippiensis et texana, erecta, subsimplex herba pilis oppositis, ramis minutissime puberulis axillaribus, pauciflorus, foliis minutis albidis, exauriculatis subsessilibus

Dipteracanthus micranthus

Stem woody below — the Ozarks & Colorado (Also in similar situations St Louis, Mo (Engl. and Alabama (Buckley) J.D. — Stem erect 15 to 30 inches high smooth; leaves ovate lanceolate attenuate into a short petiole smooth, shiny or slightly, 4-5 inches long 1/2 to 2 inches wide; flowers sessile about 3 flowered in the axils of the leaves, each subtended by one or more few flowered cymes subsessile or pedunculed in the axils of the leaves, flowers pedicelled; calyx segments hairy, subulate nearly equal as long or longer than the tubular corolla, corolla 4 to 4½ lines long those that I could examine, have an obscurely which is nearly equally 5 toothed, teeth rounded; stamens included, filaments in the flower as which into a knee the superior one I examined always twisted bent so that mouth the anthers appear nearly on the same level; style hairy, stigma subulate obtuse glandular only on the upper surface with a stigmatiferous tooth or small division Capsule 10 lines long, roughly unguiculate, smooth, about 7 lines long



with 8 parallel veins. — ~~Near Cuyotlan~~

Here I add a little description of another singular Acanthacea already described last year. It is very distinct on account of the singular Corolla but it has four anthers and all four ~~ill~~ complete with 2 cells, still Mr Linden observes that sometimes 2 are wanting; — probably belongs to the first section of Justicieæ End pg 793 and bears on account of its ovule coiled about the same relation to them as ... to Ruellieæ; near Cuyotlapampam

Adhatoda ... .

subæqualis corolla hypogyna bilabiata, ~~labio~~ tubo recto, ~~faucem~~ dilatato, labio superiore bifido, inferiore trifido, stamina 4 (~~2 sterilia~~) corolla tubo inserta didynama subinclusa antherae bicellares, parallelæ, ovari — bicellare, loculis multiovulatis, stylus simplex, stigma subulatum ~~integrum~~ bifidum, capsula (12 — 20) sperma loculicide bivalvis, valvis medio septiferis, semina retinaculis uncinatis subtensa.

Hasta pulverulenta, ~~glabra~~ ramis tetragonis, ~~simplex~~ radicans, foliis petiolatis longe lanceolatis, floribus in axillis foliorum ~~glomeratis~~ parce sessilibus, corollis minutis, calyce aequantibus. —

In swamps near Houston fl in October. —

~~Stems~~ stems erect simple rooting at the lower joints, or decumbent & branching, ~~and~~ leaves linear lanceolate branches simple; 4 to 6 inches long ½ to 1 inch wide acute attenuate at base, sessile — spikes flowers clustered in the axills of the leaves, closely sessile — calyx segments ~~5~~ nearly equal ~~unequal~~ subulate, about 3/4 lines long; corolla

In clayey soil near Industry July to
Sept. — Also along the Mississippi, Arkansas
and Missouri in alluvial sandy or
generally black heavy soil. — Perhaps the
smallest of our prostrate Euphorbias, leaves
from one to 2 or 3 lines long, stems about
½ line long; nearest to Elliott's *E. serpifolia*
but much smaller — all parts, flowers
more crowded, ✗ stipules, more entire

Mixed with this plant were another species
which I believe is undescribed I have found
the same — Prof Short's Collection sent from
by Dr Hale under the name *E. rotundifolia*
but as ~~I notice~~ this is a name already
used — & the leaves are frequently more oblong
than round I have called it

E. oblongifolia n.sp. Euphorb.

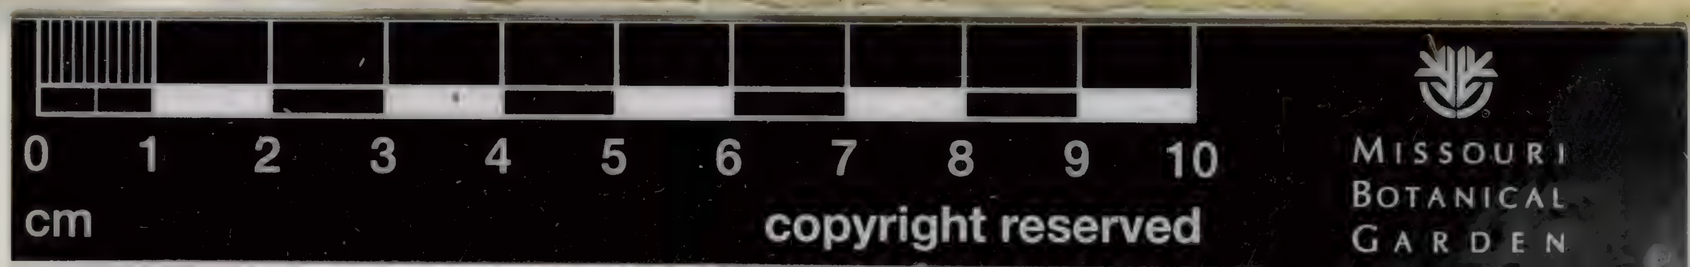
besides these on the following we have about
10 more Euphorbias with opposite stipulated
leaves in the U. States, which are partly

oval or elliptical deeply
cordate at base,
obtuse

Stem 2 inches long 1 or 1¼
wide

robust 6 lines long

✗ petaloid appendages
small transversely oval and
emarginate



difficult to distinguish. But their seeds furnish some very good characters; they may be divided into two classes: 1, with smooth reddish gray seeds, and entire and glabrous leaves and 2, with uneven tuberculated rugose or foveolate reddish gray or blackish seeds and serrated smooth or hairy leaves. All these are annual. But there is one ~~collected~~ species on the upper Platte river towards the Rocky Mountains which I call E. dellavidea which is perennial has smooth entire leaves but foveolate seeds, therefore in many respects very different from all the others.

301. MISSOURI BOTANICAL GARDEN

generibus singulis v. binis. Fem. calicibus v. i. dilatatis saepius 4-partitis, alyc. 5-fidis, aequalibus. Discus orbiculato-ins. crenato stylis 3 ter bifidis stigmatibus sub 24; capsula dense sericeo tomentosa, tuberculosa. —

Prairies of the Colorado — Cotton staminate & female plants often generally intermixed and covering large patches of ground. —

An annual about 3 feet high. — Leaves above and below stellate pubescent, but below much denser, and whitish; 1½ to 2 inches long, and 3 to 5 lines wide; length of petioles equal to the breadth of the leaf. * Capsules covered with tubercles, on which the stellate hairs are more crowded, which gives it very various appearance. Seeds nearly orbicular, compressed, about 1⅛ lines in diameter. — Near Nuttallia multiflora Torrey & Fremont's report 1843 but with fewer flowers apparently well ripened seeds. — This last one of which I have only a male specimen collected by Dr Wislizenus 1843. on the upper Platte river, has leaves smooth above and the entire pubescence not so dense; it has the male flowers in a dense compound spike the single flowers are larger, nearly twice as large, and have only 7 to 8 stamens, still on an orbicular not five lobed disc. — Is Nuttall's plant (cited by Torrey Ill. 266) unspotted on the posterior petal?

* divisions of 20 to 24 stigmas

Cr. [illegible] No 172. Cr. glandulosa. = Jaisleria glandulosa Klotzsch but the calyx of the male flowers 5, not 4 parted, with 9 to 10, not 8 stamina.

Engelmannia Klotzsch has a 3 not 5 parted calyx of male flow. 3 not 5 petals, 3 to 6 not 5 stamina; that of fem. fl. 4-6 parts, not 5 (vide Endlicher 5-226, 1)

What new genus does Croton maritimum belong to? I can not find any in Endlicher that suits it. it has 12 stamens but no petals; calyx of fem. flow 5 or 6 parted. Is it a Tenderanda? but not dioicous! —

Cr. argyranthemum appears to be a true Croton but stamens 8 to 12 on an orbicular, not 5-glandular disc

178 Jatropha stimulosa is Chidrosolus

306 Fragia humilis

306 Pargoreton humilis n. sp.

Pargoreton n. gen. :: flores monoeci. spicati s. glomerati. Masc: calyx 5 (raro 6) partitus, subaequalis; petala 5 spathulata, calyce paullo longiora, alterna, disco 5 glandulos insidente, glandulis subulatis, filamentis inferne ± columnatis, coalitis, superne filiformibus, distinctis, bidentatis, ventrosillatis, antheris bilocularibus, versatilibus. Fem. calyx petala nulla, disco 5 glandulae subulatae, calycis laciniis oppositae, ovarium sessile, triloculare, uniovulatum, stylus bifidus, lacinis bifidis, stigmatibus 6, capsula trivalvata, valvis bivalvibus monospermis, semina globosa rugosa!

Herbae perennes, laxae, pilis bifidis vestitae s. glabrescentes, foliis alternis, integerrimis, petiolatis, rotundo-ovatis, basi cordatis, margine glanduloso-ciliatis, floribus axillaribus, glomeratis, pedunculis (paucis) ad basin spicae, petalis purpureis, calobo

Nomen habitus Fragine et affinitate Crotonis referens

especially near D. taxis Vahl, but distinguished by the glandular disk, the smaller number of stamens, the shape of the stigmata and the wrinkled seeds

Fragoreton humilis caulibus pluribus adscendentibus, parce pilosis, a basi ramosis, foliis ovato lanceolatis, breviter petiolatis, ad apicem pilosis, margine glanduloso-ciliatis, floribus axillaribus

foliis multo brevioribus
pauciflora — ad basin flore foemineo v unisexuo;
petalis 4 flore foem. subulatis
glandulis brevioribus; ♀ fl. masculo calyceo
puncto suprapetalo; petalis oblanceolatis capsulis adpresse
seroso-tuberculosa rugosis.

In hard clayey soil east of the Bayou
for March to August. — The smallest
of the 3 species known to us; 6 inches high,
easily distinguished by the small leaves (1 to 1½ inches long
glomerate flowers, and small seeds (nearly ½ inch wide)
(which are hardly more than one line in diameter)
and are minutely tuberculate under a glass.
& rugose and striate under a glass.

The staminate are connected in a column
upper part free 4 or 5 flowers in a cluster
& terminal and 2 or 3 an upper axil. simplicibus

175. Tragia ramosa erectus caulibus erectis pilosis
foliis ovatis serrulatis, supra denique glabris pilosis
spiris axillaribus, foliō multo longioribus
multiflora fl. foem. pauciflora, inferiores sub bifidis distantibus superiores
obovatis. fl. masculi flavescentes;
petalis oblanceolatis calyce aequantibus; fl. masc.
glandulis minutis pilosis, pedicellis subulatis obtectis
glandulis setaceis obscuris, pilosis; petalis
nullis; capsulis lanatis tuberculato
rugosis.

On dry prairies with hard soil, on the banks
margins of Creeks, east & west
of the Bayou. fl. May to July. — Stems, stout
12 to 18 inches high; leaves 1¼ to 2 inch long,
¾ to 1 inch wide, very hairy below
spikes on long pedunculed & lateral, long on the
the leaves. spikes long pedunculed, naked below
Spikes about 3 inches long, naked for the lower half;
about 2 female flowers, below distant-
male flowers about 8 or 10 on the above
approximate. male flowers (about 1 line long
with broad acute dull purple petals;
seeds about 2 lines in diameter.

Besides these we find mixed up with
the latter some specimens of a third species
which we call Tragia glabrior dioicus caulibus pluribus erectis simplicibus v. superne
ramosis foliis ovato-lanceolatis supra glabris subtus
pubes ad venas foliorum, spiris axillaribus,

nulli floris

Corys pedunculatis masculis elongatis, folia multo superantibus; femineis brevibus, pauriflorisfolia vix excedentibus; rare monoecis, infra femineis supra elongatis masculis. fl. mas. petalis oblongis antice calycinis, glandulis glabris, fl. fem. glandulis subulatis antice, glabris, petalis nullis, capsulis adpresse tuberculatis seminibus levissime rugosis.

On banks of Creeks near the last spring; May to July — Near the last spring in with which it may be confounded, but will distinguished by being nearly always dioicous, by the more slender leaves, with berefinely to gether with the stem quite glabrous, the larger flowers the ripe, pubescent capsule the less wrinkled nearly smooth seeds. — Stem to 12 inches high. flow leaves in size and shape the last species; flowers twice as large, only 4 segments of petal about 2 lines long; seeds barely two lines diameter. — male female those that bear flowers (of which we have only a single specimen) 3 inches long and 2 lines in diameter spike of the female plant 1 to 1½ inches long with 2 to 3 flowers seeds about 2 lines diameter rather smaller than the last species.

307. Tragia brevispica n. sp. multicaulis ramosa, adscendens procumbens, aperibus subvolubilibus, ramis apice flexuosis, volubilibus; foliis e basi cordata triangulari lanceolatis, irregulariter dentatis dentibus parce pilosis, petiolatis; spicis foliis oppositis multo brevioribus, monoecis ad basin unico masculis pluribus; capsulis hispidis.

In black clayey soil in the Prairies west of the Rivers. In this all the Tragiae the spikes terminate the branches or become more frequently (by the elongation of the axillary shoots) opposite to the leaf sometimes they appear to come out of

with 20 to 30 flowers

MISSOURI BOTANICAL GARDEN

the stem above the insertion of the leaf or — of the
word, their corm peduncle is coalescing with the stem.
— This species is nearly related to T. cuneifolia
but distinguished by the procumbent stems, which of
forms bushes of 2 feet or 3 feet = diameter
which are frequently twisted or clubbed at
their extremities; by the much narrower leaves
(for 3/4 to 2 inches long — & for 2 to 6 lines wide
but especially by the short spikes (= 3 to 4 lines long) & small
flowers & fruit, which are thinner & less crisped.
The diameter of the seed is 1 1/2 / 10 of a line
— that of T. cuneifolia 1 1/5 — nearly 2 lines
(by Lindheimer № 5782 Called the flowers axillary
though = the next genus he says "spikes opposite leaves" —
as it is in this —

308 Forestiera acuminata Poir On the banks of
the Brazos, near Independence. March 1844
I have found the same plant, on the Trinity, Illinois
Mississippi; Neosho, & Arkansas rivers. —

NB. Among Lindh. former collections is a plant
evidently near Forestiera; a pubescent shrub, with
opposite leaves; similar inflorescence, but
flowering in Summer. in the axills of the numerous
scales are 2 to 4 staminate & pistillate flowers
and sometimes hermaphrodite or fecundle flowers
with the; I have seen fertile flowers with 1 stamen
— with 2 or 3 stamens; ovary 2 capellar, with
2 styles. —

U. crassifolia Nutt.

Ulmus — flowers in Sept, leaves small
but obtuse, segments of perigon 8, green
ovary villous — by the narrow segments from
all the ulmi distinguished!

309. Quercus obtusa Nutt Sandy & hilly soil
forming groves in the Ravines; together with
Q. obtusiloba. Fl. Febr. — The earliest flowering
species in Texas, Never a large tree, often
crooked, very much branched, unsightly
except in spring when the silvergray
leaves with the reddish tops form an
agreeable contrast with the fresh green of the
prairies.

20 May

311. Potamogeton ~~flavescens~~ natans L. var.? v

~~ovalibus petiolatis~~ infimis submersis elongato-lanceolatis, ~~ovatis~~ utroque acutiusculis petiolatis, ~~brevius~~ petiolatis, superiorib⁹ longius petiolatis, semiamplexicaulibus, ~~ovatis~~ oblongis, ovatoellipticisque summis natantibus, elongis, obtusis, pedunculis aequalibus, fructiferis erectis, fructibus biliniari compressis, margine antico rotundo, ~~subacuto~~

In clear water, especially in pools formed by slow runs & rivulets west of the Bayou St. Denis. It ~~this plant~~ is apparently distinguished for P. natans by the long petiols of the upper — & very short ones of the lowest leaves which are very narrowly lanceolate. also by the more elongated & mostly somewhat acute upper leaves, but principally by the acute margin or carina of the fruit; — in this respect it approaches P. flavescens; — We have a similar form in the lakes ~~&~~ on the high ground near St Louis. ~~fruit entirely the same~~ swamp ~~upper~~ leaves (~~ovate-elliptical petioled~~ ~~similar~~ but not always present; Spikes mostly — the axills of the lanceolate nearly sessile submersed leaves; — This ~~It~~ the species without the upper ovate leaves (which ~~give~~ make this appearance only after flowering) are difficult to distinguish from Potamogeton lucens L, and may possibly be a variety of this.

310 Potamogeton diversifolius Dietr. Spec. Fil. Jour. 46. pag. 102. ~~with the following~~

In clear ponds — pools & ditches Swamp near Carondelet ~~Spec~~ Specimens ~~from~~ St Louis; April. — leaves from 5 or 7 to 13 inches!

312 Xyris brevifolia Mich. Spec. ~~Swamp~~ Pl. ~~Swamp~~ plains near Carondelet — May. — I have seen this same Specimen under this name sent by Dr Hale from Louisiana and it agrees better with Michaux's description than any other I have seen so that I conclude it may be Michaux's plant. — Stems 12 — 15 inches high, twisted

311 slightly compressed with two prominent smooth angles not thickened below the [illegible] + [illegible] globose. scales v. obovate ~~regularly fringed~~ ~~notched~~ slightly crenulate. two lateral sepals slightly, irregularly fringed & notched on the back. —

X Leaves retaceous, twisted, 4 to 6 or 7 inches long.

I can distinguish 8 species of Lycium in my collection; 5 of the are texan ~~two~~ other eastern (carolinianis of N York bursifolia "Curtis N Carol.) and one (fimbriatus "this" not Elliot) from Louisiana. ("It is easy to class them according to their stem, which is 2 or many angled angles ovaries or smooth; fruits, & lateral sepals.

313 Lycium minus n sp. ramis axillaris ramosis foliosis, spathaceis parvis inaequalibus flores ~~subsuperantes~~ aequantes v. paulo excedentes, perigonii segmentis (coeruleis) ovatis extensis reflexo-mucronatis, capsulis ovatis globosis

Many of the stag nant waters in the Prairies west of San Felipe. Sept. — Distinguished from the other kinds of Lycium by the smaller size of all its parts, the much branched stem, the ovate not obovate & emarginate lobes of the perigonium and the oval, not globose capsule. Seeds ~~globose, impressed~~ dotted, black. stem 4 to 6 inches high, leaves mostly fascicled 1 - 2 inches long, spathes 8. to 12 lines long, flowers when a little shorter than the fruit, axils, not unusual ovate one, with about 4 flowers of the same length, on a little shorter, nearly round body; ~~bracteal~~ spathes often flowering increasing in size; segments of perigonium blue, about 2½ or 3 lines long; capsules small ovate or obovate, 2 p lines long and 1½ lines diameter, seeds numerous very small, impressed dotted, black.

N. Am Mexican, № 189 must belong to a Genus not described by Endlicher, though certainly a known plant, as it is very common in Texas and in flower all Spring & Summer. — It is distinguished by the broad Connecticum between the cells of the

6.

3/4 Amaryllis Lindheimeri ; x 1/2. foliis
linearibus ~~enatis~~ planis, scapo uniflore
foliis superante, ~~spatha tubuloso bifida~~
flore intus spatham tubulosam, bifidam
pedunculato, pedunculo exserto,
perigonii ~~tubo~~ infundibuliformis, tubo recto, limbo regulari
erecto, staminibus inæqualibus inclusis,
stigmate trifido, capsula subglobosa,
globosa, seminibus pluribus compressis
alatis angulis.

In black Lagey soil in low parts of
the Colorado prairies ; generally
many together ; flowers ± Sept. Sepals
petals inside yellow, outside reddish
orange. — A small but very pretty
bulbous plant, leaves 2 or 3, inches long
1/2 to 1 line wide, scape 2 to 3 inches long
spatha about 9 lines long, acuminate ;
1 to 1 1/2 inch long ; flowers 12 to 14 lines long ;
capsule abt 4 lines diameter. —
A Amaryllis, belongs probably to Zephyr-
anthes Herb. (Endl.) ; with an extremely
short tube.

If another described genus, I should
like to call it Lindheimeri

Spatha 1 - 1 1/2 inch long.
segments of perianth 1 1/2 inch long
Leaves 3 to 4 lines wide

NB. Besides the Cooperia No 196
Lindheimer has sent a second genus,
of which you get also the bulbs
it is distinguished by flat broad leaves,
larger flowers, but especially by
pedicellate flowers ! peduncle - the

flowers in cluster, upper stamen much shorter the lower ones included ; — perigon lurid, yellowish green with darker yellow stripes lines. — flowers always half closed.

5. Lindheimer Collect. 1844.

Among the Coopsia with sessile flowers I have two, according to the size of the ~~stalk~~ width of the leaves; one has ⅓ to ½ lin. wide leaves the other 2 lins wide and more undulate; but with this is a different flowering I do not know. —

~~315 Allium~~

199. Allium mutabile Mich. Shady moist places on the Bullcreek April & May. — Spring Leaves. the three collected 3 near Houston; from 12 to 20 inches high. Bulb tunicated reticulate ~~Capsule~~ with a crown of 3 scales which disappear on the ripe capsule in this respect dissimilar to All. angulare Curtis) — A. stellatum Lins where of the 6 scales remain on the capsule as a crown. Ovary with 6 ovules, capsule with one to 3 seeds. —

315. Heleocharis ? near Houston

palustris, Mc Clorack, March. — Very near H. capitulata but stems stouter, more angled, spikes larger with more scales more equal — with Chaetothec. the lowest is much larger the others — & complexly green with membranous margins ~~ribbed~~ nerved (not brown & without ~~ribs~~ nerves) 3 oblique nerved with 3 slender bristles at base ~~&~~ in bladder finely transversely wrinkled. — (no bristles = H. ac ?

316. Fissarena cylindrica Mich Prairies, west of the Brazos, April & May. —

317 Andropogon macrourus Mich On mullets near the Colorado Sept.

Setaria glauca of S. Carolina Pinkney

318. Cham polyphylla A. Braun L. Michauxii. — On clayey soil & clear rivulets — the Prairies between the Brazos & Colorado July — & the whole year round. —

~~The enclosure has entirely~~

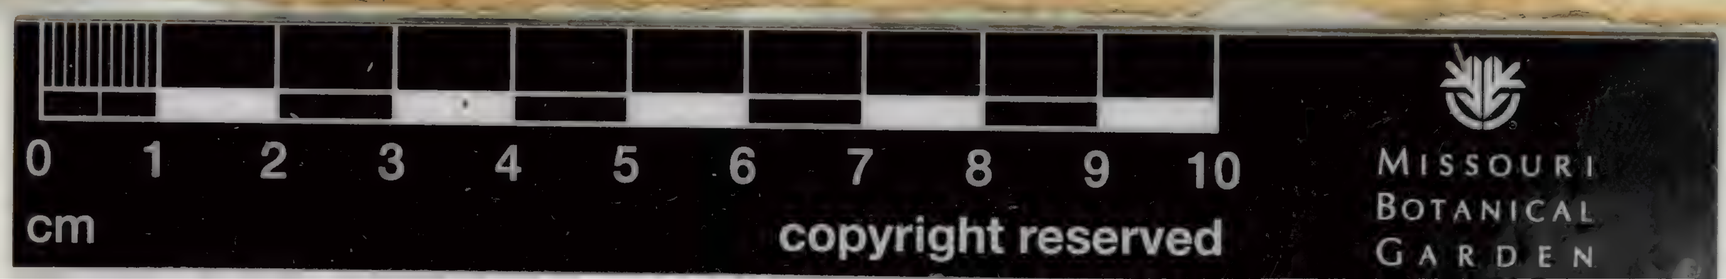
In addition to the [illegible] enumeration of Northamerican Charae published in this Journal, Vol. 46 pag. 92 (Jan. 1844) we [illegible] to add [illegible] that we have obtained specimens of Ch. flexilis also we think it proper to add a few notices communicated by Prof Braun.

Mr Lindheimer has sent for Texas specimens of Chara flexilis Lin, (too incomplete to be fully determined) and of Ch. leptosira Desv. this as well as the species fr Massachusetts, may be distinguished as var. americana. the verticilli are less densely glomerate but more approximate than in the european form. —

Chara polyphylla A. Br. is a very polymorphous plant occurring in many different forms in [illegible] Mr Braun distinguishes 7 subspecies

a. Ch. polyphylla Millaceii (Ch. polyphylla A. Br. in Regensb. bot. Zeit 1835 pag. 70. Ch. Michauxii A. Br. in Schlecht. Linn. l.c. N.o 11 Ch. capillata Michaux in herb. Jussieu. Ch. haitensis Turpin Dest. Sc. nat. Atlas) Ohio, Michaux. Dr Frank Missouri (Dr Engelm) Texas (Mr Lindheimer) Hayti (Turpin 1796). This is the slenderest and the most northern of all species & subspecies of the very remarkable group of Gymnopodae A. Br. There are 5 species now known belonging to this group, and of these Ch. polyphylla is the most polymorphous and widest spread species. — The Gymnopodae are distinguished by having the lowest (often very short) joint of the otherwise coated (or incrusted) leaves (commonly called verticillated branchlets) naked or destitute of the coating.

b. Ch. pol. guadelupensis (Ch. india Bertero) Guadeloupe (Bertero); more slender with smaller more elongated seed vessels (sporangia) and still shorter basts.



c. Ch. pol. ceylanica (Ch. ceylanica Klein in Willd)
Ceylon, Pondicherry, Madras etc

d. Ch. pol. javanica.

e. Ch. pol. Muhlenbergii (Ch. foliosa Muhlenb. = Willd) also Sill Jour. L.C. 17.93 No 10
Pennsylvania Muhlenb. Very near subspecies c, ceylanica,
as distinguished from a, Michauxii by
the bracts being much longer than the sporangia
while they are shorter in pinnacea.

f. Ch. pol. Humboldtiana (Ch comprissa H.B.K.)
New Andalusia, Humboldt. A variety with
some of the upper joints of the branchlets
destitute of the coating.

g. Ch. pol. armata. (Ch armata Meyen. Reisebericht)
Sandwich Islands Meyen. distinguished by
strong spines and also mostly naked
upper joints and smaller seedvessels.

A second
Another species, distinct from Ch. polyphylla but also
has been collected by Dr Engelmann belongs to the Gymnopodae
in the lakes in the bottom lands of the
Mississippi near St Louis; it is called
by Prof Braun

Ch. tejunata, distinguished a more
slender and greener plant than
Ch. polyphylla but principally distinguished
by the seedvessels (sporangia) and globules
(also called anthers) being always
four on different joints of the leaves
(or branchlets) never as in most of the species
together on the same joint. Martius
has collected the same species in Brazil
the Nictheroy form has bracts shorter
than the seeds, and may therefore be
called var. brevibracteata, and the
Mexican long-bracteata.

N.B. a Lemna which I have sent to
Prof Brown from here is well as for Mr Bauer
under the name of L. polyrhiza for
which I took it, but may have been by him
declared to be a new species and
called Lemna umbonata

Sandy wet prairies Houston Texas Apl. & May

5'- 12 heads (yellow 15-25) but dry 20-30 (.10-20 rays

Different from mucronata by the short spike, the larger

~~heads~~ (5-7 rays long), lanceolate scales

much larger smooth or a little scabrous

fruit, which is not shorter than and equal to

the pappus - color by the leaves dilated

base which in L. mucronata is only the

case in the ~~basal~~ inferior leaves - and

callous and rather obtuse (not very acute

at tip. ~~Ap~~ and probably time of flowering

April & the other in July - August.

2f Echinacea grandiflora? what is the difference

of this and coronata? outer scales

involucre also white! Achene 4 sided

winged

2g Echinacea angustifolia DC. = E. pallida Nutt. very

similar to E. sanguinea Nutt, which I take to

be the common form in Missouri & Illinois. -

there is perhaps some difference in the seed:

E. angustifolia is a much smaller plant

Peduncle long, hardly thickened at top,

head hemispherical not conic at all, rather

somewhat flattened Apl in Texas

April & May. rays 1½'- 2½ (usually 8-13 more or less 2-3 inches)

E. sanguinea is stouter;

peduncle long, incrassate for some distance

below the head, and sometimes immediately

below it - head as large again, hemispherical

and somewhat conical; fl. about St Louis

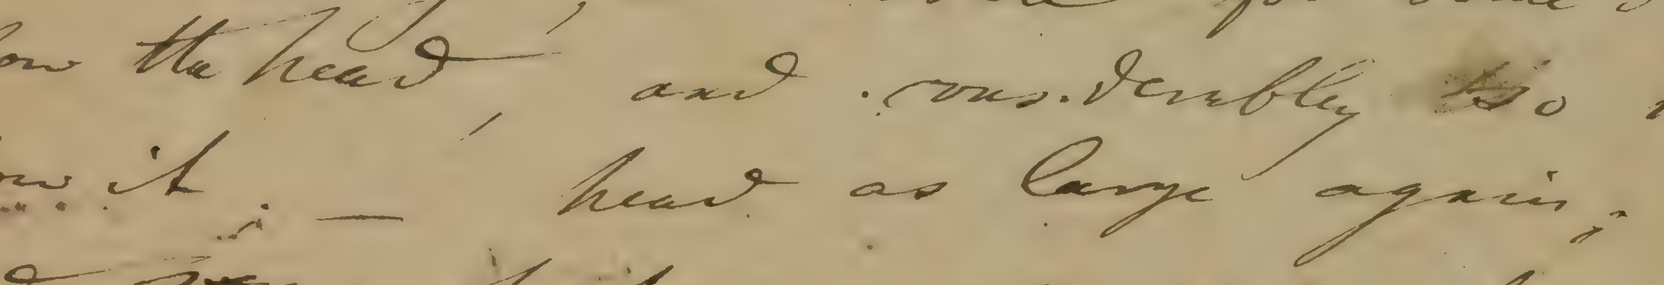
in May & June rays 2-2½ inch long

Aplopappus phyllocephalus DC Galveston Island

fully corresponding with DC Description but

~~leaves~~ Achenia silky villous not glabrous!

(but the same mistake appears to have been made



Astragalus spinulosus !

31 Helianthus occidentalis n. sp. similar
to H. argyi foliis; stem more simple, leaves narrower, spreading or recurved, very scabrous above & hispid beneath — Disc brown, not purple, disk flowers with long exserted Anthers. (i.e. same length with the corolla) tube of corolla smooth not pubescent as long as neck, (not half as long) only tip of segments of corolla purplish pappus, and pubescence the same in both.

73. Tephrosia argentea n. sp. caule erecto pubescente villoso, foliis petiolatis; foliolis 13–21 oblongis 6–10 jugis retusis emarginatis ve mucronatis supra glabris reticulatis subtus adpresse argenteo pubescentibus stipulis subulatis persistentibus; pedunculis elongatis pauciflorus; calyce albido villoso segmentis triangulibus subaequantibus, vexillo oblongo elongato

70 Astragalus flagellaris n. sp. caule procumbente glabrescente, foliis petiolatis 7–10 jugis foliolis (glabris) oblongis retusis v. emarginatis (mucronatis) pedunculis folia superantibus, floribus laxe capitatis capitulis flore laxis ovatis 8–15 floris; calyce petiolato pilis albidis brevibus sparsis adpressis subpubescente, dentibus triangularibus, vix dimidia tubi longitudine, v. leguminibus glabris reticulatis oblongis (mucronatis) sutura superiore inflexa sulcata. — Distinct from Astragalus by the calyx teeth and inflexed sutures of the pod from Oxytropis by the strongly reticulated pod valves.

N.B. some leaves less reticulate than others! vide below
